Behaviorists in Community Work	680, Adv. 46
Belgium, Child Welfare in	599
Bettman, R. B.—Flat Foot as a Problem of Industrial Surgery	461
Bettman, R. B.—Industrial Surgeon and Individualization	423
Bibliography on Industrial Hygiene	
Biology Through the Movies	70, Adv. 28, Adv. 39
Birth Control Conference	39
Blessing, George F.—Pioneer Work of, on Fatigue Examination	675
Blind, Sensible Aid for, at Chicago Lighthouse	Elith L. Swift, 470
Blindness, War, Statistics	Industrial, Edward Stieren, 368
Bocser, Dorothy—Child Hygiene Activities in Georgia	242
Bobby, Emma C.—Group Consultation Clinic	35
Bolivia Provides School Medical Service	686, Adv. 44
Boothby, Walter M.—Laboratory Manual of the Technique of Bacteriological Rate Determination	70, Adv. 20
Bose, Life and Work of Sir Jagadis	Patrick Golden, 69
Boy Scouts Begin Their Busy Season	328, Adv. 60
Boyd, Dr. Mark F.—Practical Preventive Medicine	397
Brintnall, R. A.—Standardized First Aid in Industrial Plants	543
Brown, Philip—King Vocational Training vs. Occupational Therapy	536
Brown, W. Herbert, and White, Charles F.—Atlas of the Primary and Cutaneous Lesions of Acquired Syphilis in the Male	68
Bryn Mawr to Hold Second Workers' School	680, Adv. 44
Buildings, Crowded School, a Health Menace	636, Adv. 42
Buildings, Urban School	328, Adv. 61
Bureau, Children's, Planned in Japan	382, Adv. 42
Bureau, Hospital Library and Service	Donelda R. Hamlin, 327
Bureau, Hospital Library and Service	636, Adv. 42
Bureau, Mental Hygiene, Established in Delaware	328, Adv. 34
Burlingame, C. C.—Work of the National Industrial Conference Board	511
Burnham, A. C.—Child Welfare Station in France	388
Medical Welfare Work in Small Factories	90
Burns, Deformity Following	12
Burns, Treatment of Acid and Alkali	A. K. Smith, 232
Buzby, B. Franklin—Defects Affecting Fifteen Hundred Men	612
C	
Cafeteria, A Shipyard	680, Adv. 30
Cafeteria System, Advantages of	Emma R. Baker, 536, Adv. 46
California Labor Camp Code	371
California, Labor Camp Sanitation of	R. Justin Miller, 616
California Society Meets	328, Adv. 44
Calver, Homer N., and Tobey, James A.—National Health Departments in Review	391
Camp, Health Matters Concerning the Summer	Captain F. L. Beals, 323
Camp Roosevelt as a Boy Builder—Lilian Ewertson	9
Campaign for a Safe Fourth	382, Adv. 36
Campaign for Cancer Control	595
Campaign for Eye Care	328, Adv. 32
Campaigns, Spring Planning of Summer Health	356
Campaigns, Traveling Publicity	53
Camps, Infectious Diseases in Summer	D. L. Richardson, 379
Canadian Red Cross Society	187
Cancer Control	236
Cancer Deaths Increase in Maine	181
Cancer in City and Country	586, Adv. 38
Cancer in Germany	653
Cancer, National, Week	536, Adv. 28
Canned Meats, How Food Values Are Conserved in	George W. Trainor, 645
Capper, Arthur—Universal Physical Education is Essential	280
Carbon Monoxid Poisoning, Chronic	Georgine Luden, 102
Carbon Monoxid Poisoning, Chronic Its Immediate and Subsequent Manifestations	Georgine Luden, 167
Cardiac Association Makes Report	264, Adv. 34
Care for Convalescent Cardiac Children	Mrs. Benedict Erstein, 631
Care of Cripples	264, Adv. 36
Care of the Indigent Tuberculous	264, Adv. 32
Carman, Russell D.—Roentgen Diagnosis of Diseases of the Alimentary Canal	264, Adv. 21
Carmody, Francis J.—National Red Cross Convention	597
Catalysis and Its Industrial Applications	382, Adv. 52
Cause of Infantile Paralysis	4
Causes of Work Accidents Among Women	Nelle Swartz, 367
Census of Chicago Boys	105
Certificates to Wet Nurses	328, Adv. 58
Chace, A. E.—St. Louis Southwestern Railway Medical Service	515
Chagas, Carlos, Visits the United States	330
Characteristics, Differential, of Species	382, Adv. 68
Cheek, O. H.—Visualization of Public Health	636, Adv. 24
Chemical Analysis of the Blood	586, Adv. 44
Chemistry and Analysis of Drugs and Medicines	Henry C. Fuller, 264
Chemistry, Creative	Edwin E. Slusson, 69
Chemistry, Newer Methods of Blood and Urine	R. B. H. Gradwohl, 110
Chemistry, Physiological	Albert P. Mathews, 70, Adv. 20
Chemistry, Text Book of Organic	A. F. Holleman, 139
Cheney, Howell—Medical Service as Affecting Industrial Relations	512
Chicago Nurses Club and Directory	118
Chicago Policlinic Expands	184
Chicago Presents Health Pageant	536, Adv. 42

MODERN MEDICINE

A Monthly Magazine of Medical & Health Progress for Physicians
& for Others Interested in Administrative, Industrial
& Social Health Problems

Editors, ALEXANDER LAMBERT, M. D., S. S. GOLDWATER, M. D., and JOHN A. LAPP, LL.D.

Managing Editor, JOHN A. LAPP

Editorial and Business Offices, 22-24 EAST ONTARIO STREET, Chicago

Volume III

January, 1921

Number 1

THE HEALTHIEST YEAR

THE year just closed will probably be recorded as the healthiest year in history. Figures from important centers and dependable sources indicate a death rate lower than that of 1919—when only 12.87 per thousand died,—the lowest rate ever known for the United States or for any large country in the world.

The principal decreases appear at the present writing to be in tuberculosis, infant diseases, and contagious diseases; but, when the records are definitely made up, we do not doubt that marked decreases will be found in the number of deaths from degenerative diseases. The decrease in tuberculosis has been attributed by Commissioner Copeland of New York partly to the decrease in the use of alcoholic stimulants. If this be so—and we do not doubt it—then how much more may we expect the same cause to affect the rate from degenerative diseases? How much more may we expect also in the future when the elimination of alcoholic stimulants becomes complete and particularly when their chronic effects in the bodies of thousands are eliminated by care or by time?

But the favorable condition for the year disclosed by the mortality statistics are not to be attributed to a single important cause; they are due also to the wider diffusion of health knowledge and the better organization of machinery for the protection and promotion of health. The year 1920 has seen the extension of health education and protective measures more widely and effectively than ever before. The vast war machinery of great welfare agencies, public and private, has begun to function for better health, and the humanitarian spirit which was the marvel of the war has furnished the impetus for a campaign which is being directed against disease.

Public health departments have been more liberally supported and sympathetically helped; public health nurses have increased greatly in numbers and in effectiveness of attack; hospitals and dispensaries have broadened the concept of their work; health centers have been created as means of education and of coordination of medical facilities; industry has recognized that health is the key to industrial efficiency; rehabilitation of the disabled has become firmly fixed as a social policy; and the physicians and surgeons, broadened by the war contacts with humanity in the mass, have found a new zeal for service to all the people. Probably never before have so many causes conspired in a single year for health. We see the effects in lives saved and disabilities prevented or cured. Moreover, the effects are cumulative. Results of the work of 1920 will be reflected in succeeding years. We do not doubt that we are merely in the beginnings of organization for better health, the results of which will be reflected in a constantly decreasing disability and mortality rate.

NATIONAL AID FOR MATERNITY

THE new year is ushered in by the enactment of the Sheppard-Towner bill providing national aid for maternity. The bill passed the Senate on December 16 with amendments which will doubtless be adjusted in conference between the two houses. In all probability the bill will be a law by the time this issue reaches the reader.

The essential feature of this new act is the appropriation of federal money to the states on condition that the states receiving the money appropriate a like amount for the organization of facilities for the education and care of mothers before and during childbirth. The primary aim is to

provide for those who are remote from modern facilities for prenatal, natal, and postnatal care. It means eventually that maternity care will be extended to every expectant mother, including nursing service, medical attendance, and hospital care when necessary. It means a vast educational campaign for the instruction of mothers in prenatal and postnatal care conducted under public auspices.

The new law has a significance far beyond the limits of present appropriation and plans. It means the organization of medical service on a vaster scale than has ever before been attempted by the American public. The mobilization of medical skill for one great social purpose—maternity—will point the way to inevitable extensions, especially in the provision of infant and child care.

DEPARTMENT OF WOMEN IN INDUSTRY

PRESIDENT Wilson has appointed Miss Mary Anderson as the head of the new Bureau of Women in Industry, created by Act of Congress in the Department of Labor to perpetuate a similar bureau instituted as a war measure. The new director has been the efficient acting head of the Bureau for more than a year and her appointment to the permanent post gives entire satisfaction to those who are interested in the progress of the work.

Almost coincidentally with the creation of the new bureau comes the suggestion that it be made a bureau of the new department of welfare which, it is understood, will be created at the next session. With this suggestion the advocates of the bureau properly disagree. There is no good ground for considering the protection of women workers as a welfare undertaking any more than there is for considering the whole Labor Department as a department of welfare. No such line should be drawn between men and women workers. The new bureau should remain in the Department of Labor.

HEALTH IN INDUSTRY DEPARTMENT

THE department of Health in Industry is edited, beginning with this issue, by the American Association of Industrial Physicians and Surgeons, and becomes the official voice of the Association. It will afford an open forum for the rapid dissemination of accepted methods in the industrial medical field. The editors of MODERN MEDICINE, recognizing the great value of industrial health work, welcome the opportunity afforded the readers of this magazine to keep in touch authoritatively with the modern movement for industrial efficiency through better health.

REAR ADMIRAL EDWARD RHODES STITT

Underwood & Underwood

THE new surgeon general of the Navy, Rear Admiral Edward Rhodes Stitt, is well known to the physicians of the country as an educator, as a man of remarkable attainments in laboratory research, especially on tropical diseases, and as an inspiring leader in medical science. A long record of responsibility and achievement is behind Rear Admiral Stitt as he enters his new office.

ECONOMY IN HEALTH BUDGETS

A PROPER estimate has never been made of the per capita outlay which it would be profitable to spend for health. That there would be a wide margin between such a figure and the actual budgets appropriated may safely be assumed. To the officials responsible for the data on which health expenditures are based the aggregate looms large, while there is usually a total lack of reliable data on the cost to the community of failure to make adequate provision.

A case in point is furnished by the story of one epidemic printed on another page of this issue from figures on the cost of an epidemic of typhoid fever in Salem, O., furnished by State Health Commissioner A. W. Freeman, who is finishing the installation of a modern health system in Ohio. This cost price of a single epidemic affords the strongest possible plea for budgets generous enough to care for the simplest health needs and illustrates the value of practising so-called economies such as the city of Salem made.

PRENATAL AND POSTNATAL SOCIAL SERVICE*

BY A. LEVINSON, CHICAGO

THE author of the popular picture, "Seven Moments in a Woman's Life," should have included one more great moment in a woman's life: Pregnancy. This period lasting nine months is full of joy and sorrow, of expectation and trepidation, of hope and fear. There is something inside of the woman constantly enlarging her, but what is it? Man or monster, male or female, normal or abnormal? As time goes on, the woman's heart becomes more unstable, the expectancy more tense. To relieve this woman, to assist her financially, physically, or morally, constitutes a service not only to the future mother, but also to the child and to society.

For thousands of years babies have been coming into this world, yet to this day the exact embryological processes of the fetus are unknown nor can we foretell the sex, the health, or the development of the new being. We are confronted with a problem of life as perplexing and as mysterious as life itself. All that can be done is to prepare for the appearance of the new being, to receive it with open arms, and make life as pleasant for it as possible.

Human Inheritance Complex

It is an old saying, but it holds good to this day, that the preparation for a baby must be started with the grandparents; that unless the grandparents were healthy the grand child will not be healthy. There are, however, a few immediate preparations left for the mother to carry out, and in this she can be assisted by others, by friends, by neighbors, by social workers.

The mother should lead a normal life during pregnancy. Over-excitement and dissipation, the curse of modern life in general, are bound to have a deleterious effect on the future baby. Hard work in a factory would obviously be of no benefit to the baby. The other extreme, complete rest, as practised by some of the wealthy mothers, is, to say the least, of no benefit. It seems that the

Notwithstanding the fact that we possess fairly accurate knowledge of the fundamental factors of heredity and of the nurture which is calculated to give full expression to the desirable characters of inheritance, society has been slow to appreciate these facts and to profit by this knowledge. The baby is helpless. If the mother does not intelligently care for it, and develop in it such habits as will serve in future adjustments, the child will die, or its life will be doomed to an inadequacy and misery. Many a disease may be prevented by the instruction and supervision of the expectant mother. Only when all women are trained for motherhood will child nurture bring its full fruition in healthy childhood.

woman who does her ordinary routine work all through pregnancy is the wisest. This should be pointed out to the pregnant woman who is at a loss what course is the best for her to pursue.

The housing problem, so acute in the large cities, should be brought home to the expectant mother. It is true that some babies who have no light, nor air in the house develop to be strong men and women, but this cannot be argued as a rea-

son for bringing a child into the world in a house where there is no light, if circumstances permit better accommodations. It occurs too often that the darkest and the smallest room in the house is put aside for a bedroom for the baby, while the airiest and lightest room of the house is carefully attired with furniture for the occasional guest. It is for the social worker to point out where such inconsistencies in logic result from the style epidemic.

The necessity of consulting and engaging a physician early should be brought home to the mother. The social worker should endeavor to convince the mother of the importance of frequent physical examinations, urinalyses, and blood pressure readings during pregnancy. No matter how intelligent the woman, she may be in need of instruction in that regard. Also, the social worker should point out to the expectant mother the necessity of caring for her teeth. The tradition "for every child a tooth" has sacrificed many a tooth in the mouth of pregnant woman.

A Wassermann test on the blood of every pregnant woman and possibly, also, of the father of the future baby would diminish the incidence of lues in this world or at least would tend to diminish its severity. If the Wassermann test were made as a routine, objections would be obviated on the part of the mother or father.

Fear Complexes Pernicious

The question of whether maternal impressions affect the baby might be considered beside the mark in this advanced age, but the fact remains that many expectant mothers worry about a horse

*The ninth of a series of articles dealing with medicosociologic problems in the field of pediatrics prepared for the pages of MODERN MEDICINE, by Dr. Levinson.

they saw racing by, or a cat climbing a tree; and, while such worries may not affect the child directly, they may easily serve to make a nervous wreck of the mother, which in turn affects the nervous system of the child. The social worker may tactfully disillusion the mother on these points, and thereby save her and the future baby much hardship. Likewise attention needs to be given to the many other complaints of the expectant mother so that they may either be corrected by a physician or their ineffectiveness brought out. Here the social worker can render important service.

The preparation of clothing for the future baby is a matter of moment. The next door neighbors may have an exaggerated or a minimized notion of its importance. The social worker should know just what a new-born baby needs, and should give the mother authoritative information in this regard.

Supervision Supports the Mother

It is strange that the women who, because of lack of home facilities need the hospital most, are the very ones that do not care to go to a hospital for their confinement. A social worker may tactfully point out the advantages of a hospital to the women, thereby diminishing the chances for a puerpural infection. Sometimes the expectant mother cannot go to a hospital because she has no place to leave the other children, in which case great service can be rendered by finding a temporary home for the children. Where the woman does not consent to go to a hospital, the home may be put into shape for obstetrical work. There is no need of elaborate surgical appliances. A rubber sheet, a few pounds of newspaper, some cotton, lysol, and hot water will suffice.

The immediate care of the newborn, the dropping of silver nitrate in the baby's eyes, the general cleanliness, and especially the asepsis of the naval, properly belong to the doctor or nurse. The doctor in charge, however, may have forgotten to impress the importance of those things on the mother and there may be no nurse on the case, when again the initiative may be left to the social worker to attend to these matters. When the social worker is a nurse, it is an ideal combination.

The hundred and one questions concerning the new-born baby, the regulation of room temperature, the kind of a nipple and bottle to use, the amount of clothing to put on the baby, the amount of water the child needs—these are all questions of great importance to the mother, no matter how trivial they may appear to the experienced social worker.

As the baby's days advance, the new mother becomes more restless; the baby cries, the baby

draws its legs up, the baby falls asleep during nursing, the baby does not want to take the bottle. If only there could be someone to help the young mother carry the burden of all these problems that seem ridiculous to the outsider, but which make life more or less miserable to the mother! The grandmother may do it, but her attitude may spoil the youngster. The average grandmother is usually so overcome by the joy of seeing her life perpetuated that she fondles the baby too much. The neighbors, if not too busy to "look in," are not always well informed. The social worker, next to the grandmother, is best fitted for the task.

Then come the never ending questions as to the feeding. As we have pointed out elsewhere, most mothers want to nurse their babies; but not every mother is able to do so, so she is in need of further guidance. The social worker may perform a real service in such a case by stopping in with some sound advice.

Finally, and most significant is the mental attitude of the mother. Only one who is constantly in touch with young mothers is in a position to realize how many women break down with the birth of the first child—a collapse that is both physical and mental. It is a sad commentary on the average preparation for motherhood that many mothers become so overwhelmed by the new animal,—by its care and by their worries over it—that the anxiety becomes pathological, and just at the time when every fiber in the body should work toward one goal, the taking care of the baby, the mother becomes melancholic, does not sleep and does not eat, to her own detriment and that of her baby. This frequent occurrence is an outgrowth of modern life, of the strain of muscles and nerves before marriage, of the style, of the mode of living; with the result that, instead of being the source of joy and happiness, a baby occasionally brings dissension in a family. This is a tragic fact which should be borne in mind by any one who wants to do social service among young mothers.

CAUSE OF INFANTILE PARALYSIS

The University of Minnesota has made an announcement as a result of investigations recently carried out that the larva of the bottle fly is responsible for hog paralysis and limber neck in poultry, and that infantile paralysis is traceable to the larva of the green bottle fly. On the basis of this information university officials have sent out a bulletin to farmers urging them to protect their live stock and poultry and possibly give human help by burning and burying deeply all carrion. Results of this work are cited as an additional argument for farm and home sanitation.

It is reported in a statement issued from the Children's Bureau that forty out of forty-eight states have now adopted some form of Mothers' Pensions.

THE NATIONAL ORGANIZATION FOR PUBLIC HEALTH NURSING*

BY ELLA PHILLIPS CRANDALL, FORMERLY EXECUTIVE SECRETARY, NEW YORK CITY

THE National Organization for Public Health Nursing exists to define, standardize, and interpret public health nursing, and to encourage and assist in the development of public health nursing, especially along the lines of education and legislation. The term public health nursing is now used to express any one of the following fields of service all of which are embraced in the title, i. e., visiting nursing, prenatal, maternity, infant welfare and pre-school nursing; school and industrial nursing; tuberculosis, venereal disease and other communicable disease nursing. It may, though in a much more limited degree as yet, include mental hygiene nursing. Medical social service work may and usually does form an essential part of all.

In most large cities these activities are still operated under separate managements; but the tendency in small cities, towns, and rural communities is, for obvious reasons of efficiency and economy, toward an amalgamation of agencies and a generalization of service. An essential corollary to the latter should be an adequate consultant or supervisory staff of trained and experienced specialists to safeguard and strengthen the work of the general staff. There are notable instances of large cities adopting the same method with modifications to meet local conditions. While in the great majority of cases these projects are still conducted under private auspices, there are instances of public direction and support of each form of work mentioned above—city and town, county, state and federal agencies now being represented. However, with few exceptions, public funds are appropriated for what is known as educational and preventive nursing as distinct from curative or bedside care. But the precept of "teaching by doing" is winning its way and slowly making for coordination of curative and preventive work.

Improvement in health conditions largely depends upon a matter of perspective. Early efforts were directed singly against separate phases of the problems of public health. Reasons of efficiency and economy demanded amalgamation of agencies and broadened generalizations of service.

There gradually evolved the ideal of a central health service adequately administered by persons whose competence was in accord with their several responsibilities.

Standardization has largely grown out of the coordinating activities of the National Organization for Public Health Nursing, whose efforts toward coordination are the best earnest of its increasing usefulness.

Public Health Nursing is thus far defined in order that it, in turn, may indicate the scope of the National Organization for Public Health Nursing which is a non-administrative, consultant body. The organization is unique among nursing associations in that it is composed of non-professional as well as nurse members who are actively engaged or otherwise interested in the administration and practice of public health nursing or

the education of public health nurses. On September 1, 1920, it had 3,717 individual and 187 corporate members.

It was organized in June, 1912, and in the following November opened a small office in New York City and employed an executive secretary and one stenographer. It was immediately endowed by the Cleveland Visiting Nurse Association with an insignia, a quarterly magazine, together with the voluntary services of an editorial staff and with assurance of maintenance; and, also, with a financial sponsor who accepted the responsibility of raising its budget for the first two years. In the same spirit Miss Yssabella G. Waters, author of "Visiting Nursing in the United States and Territories," identified her statistical work with the Organization and has contributed her services and that of her clerical staff to the present time. Its object as stated at that time was as follows:

The object of this Organization shall be to stimulate responsibility for the health of the community by the establishment and the extension of public health nursing; to facilitate efficient cooperation between nurses, physicians, boards of trustees, and other persons interested in public health measures; to develop standards and technic in public health nursing service; to establish and maintain a central bureau for information, reference and assistance in matters pertaining to such service; and to publish periodicals or issue bulletins from time to time to aid in the accomplishment of the general purpose of this Organization.

Its functions have more recently been summarized as follows (being an excerpt from the "Agreement" entered into in January, 1920, by the National Tuberculosis Association, the American Red Cross, and itself):

*The fifth of a series of articles on national health organizations prepared especially for the pages of MODERN MEDICINE.

I. Educational.

(1) Assisting in the organization and improvement of post-graduate courses in public health nursing.

(2) Assisting in the production of more public health nursing teachers through a special scholarship fund.

(3) Encouraging introduction of instruction in subjects relating to public health nursing and field work into the curricula of qualified training schools.

(4) Promoting special institutes for public health nurses already in the field.

(5) Conducting a circulating package library, advisory service to libraries concerning public health nursing literature and bibliographies.

(6) Publishing the *Public Health Nurse*, a monthly magazine.

II. Recruiting.

(1) Encouraging graduate and student nurses to enter public health nursing.

(2) Encouraging high school and college students to enter nursing and to prepare through pre-professional courses. This is being done in cooperation with the other national nursing associations.

III. Employment.

Maintaining of a limited employment service which could be developed into a national employment clearing house for public health nurses.

IV. Standardization.

Studying of and assisting in establishing standards of organization, administration, publicity, and financial support, records and reports.

V. Legislation.

Creating public opinion in favor of and assisting in the enactment of suitable public health nursing legislation, such as the appropriation of public funds for public health nursing, and the creation of divisions of public health nursing within state Departments of Health.

In the beginning, the Organization's methods were frankly propagandist in character, for even the term public health nursing was new in those days and there was relatively little understanding or appreciation even of visiting nursing, from which all the later activities grew, and the newer forms of preventive work were as yet undeveloped. As compared with England and some of her colonies, America was far behind in national development of a service which some day seems destined to become a public utility comparable with the public school system.

Becomes a Public Utility

In 1910 there were still ten states in which there was not a single public health nurse, and the vast areas of southern mountains and western plains were totally unprovided with nursing care. In 1912 the 899 associations, employing something more than 2,442 nurses, represented all but two states; but were practically unacquainted with each other, and their activities unrelated. The majority kept meager records or none at all; with few exceptions their work was done free of charge and, consequently, was characterized as charity and limited to the dependent classes. Practically all the governing bodies were composed exclusively of women, and men were scarcely interested beyond giving their annual contributions when solicited.

There was practically no literature of American origin. No textbooks had been written and only one formal course of instruction was available, though several informal series of lectures and demonstrations were conducted by a few leading associations. Public health nurses had no place in the programs of the associations devoted to various aspects of the developing national program of public health, although the need of and dependence upon their work was frankly acknowledged. Nurses recognized themselves as an essential part of these various health programs, but also realized they could not function

separately or independently. Such was the status of public health nursing in America in 1912.

Whatever service the National Organization for Public Health Nursing has rendered, in the extension and standardization of the rapidly growing work which it essayed to foster and represent, its officers would not fail to point out that it has built its principles and policies and standards largely upon the experience of the older and well established local associations; and that its influence has been largely shared with and augmented by the Red Cross town and country nursing service (later the Bureau of Public Health Nursing), the Metropolitan Life Insurance Company's nursing service, the Division of Public Health Nursing at Teachers' College, and, more recently, similar departments in other educational institutions. Hence it is impossible to measure or tabulate specifically its record of achievement; but its services have been available to all who wish them, irrespective of membership in the Organization. The Organization has made no effort to dominate or control the policies of local agencies; it has sought rather to guide public opinion.

The Organization began at once to secure corporate memberships in other national health associations and a place on their annual program and in their official journals. It is now represented in the following: American Child Hygiene Association, American Conference on Hospital Service, American Public Health Association, American School Hygiene Association, American Social Hygiene Association, General Federation of Women's Clubs, National Committee for Mental Hygiene, National Committee for Prevention of Blindness, National Conference for Social Work, National Safety Council, National Tuberculosis Association, and the Women's Advisory Council—United States Public Health Service.

In addition to these affiliations, its Executive Secretary serves on the directorates or other administrative committees of the following associations: Board of Trustees, American Hospital Conference; National Committee on Nursing, American Red Cross; Board of Directors, American School Hygiene Association; Sub-Committee on Public Health Nursing, General Federation of Women's Clubs; National Committee for Coordinating Child Health Activities; Joint Committee, Headquarters of National Nursing Associations; National Council, National Social Unit Organization; and on the Advisory Board, Seamen's Service Center.

Up to September 1, 1920, there were sixteen state organizations of public health nursing. In seventeen other states, sections or committees within state associations of graduate nurses had been formed, rather than separate bodies, in order to strengthen the older associations. There is a growing tendency to identify the membership of these state bodies automatically with the National Organization.

Fundamental Requirements Defined

It has been, for the most part, inexpedient if not impossible to make pronouncements or render more than tentative judgments on many current problems and questions of policy, because there has not been time for accumulation of a sufficient body of experience on which to base more permanent decisions. But the Organization has consistently stood for such fundamental requirements as: Approved methods of raising funds; a fee system for bedside care rather than a free service; extension of service to all, especially those of moderate income; standard rules and regulations governing organization and administration; thoroughgoing records and reports; nurse supervision of staff work; standardized dress; and adequate salaries.

It has also urged the following progressive developments: Coordination with activities of allied agencies, including those supported by public and private funds; recognition of ultimate responsibility of government agencies; administrative advantages of divisions of public health nursing within departments of health; and value of citizens' advisory committees to support public departments of health in the development of public health nursing.

A few examples will best indicate the character of the Organization's service to local communities. In 1916 Los Angeles asked that a secretary be sent to reorganize its municipal nursing service, that city bearing the distinction of having no private public health nursing agencies. The Organization's newly appointed Associate Secretary was detailed for a six months service, during which time she established a complete reorganization of the work and record system, instituted a plan of coordination between the Department of Education and the Department of Health, trained a permanent executive, and laid out a program of further development which has proceeded according to her recommendations.

During 1918 Pittsburgh, where for many years a large number of separate agencies had been conducting various forms of public health nursing without coordination, realized its need of centralized service. The Women's Committee of the Council of National Defense requested the National Organization for Public Health Nursing to send a representative to make a study of its existing agencies and to make recommendations. This was done; and an organizer was secured who spent six months effecting a public health nursing association which was finally launched with the hearty endorsement of the Chamber of Commerce, the Departments of Health and Education, a number of the leading industrial plants, and of the local Red Cross Chapter.

In Rochester, N. Y., the Federation of Social Agencies and the Chamber of Commerce took similar action. In this instance a much less extensive study was required; but two consultation visits were made, an executive was nominated, and later advisory service was rendered.

Westchester County, N. Y., represented by twenty-seven agencies, also made request for a study of needs and possibilities for more and better coordinated service. This study resulted in the formation of a County Federation for Public Health Nursing which has just completed its first year with definite gains toward unity of purpose and with excellent promise of further developments.

The National Organization for Public Health Nursing has been invited by two state departments of health to lay out programs for state wide development of public health nursing. While its staff has as yet been inadequate to grant such an extensive service, it has acted continuously in an advisory capacity to state supervising nurses and other state health officials. Especially is this true in the few states where its plan has been adopted of organizing state committees on public health nursing representing both public and private agencies. These will have later mention.

The service of its Educational Committee and Secretary is perhaps as well known as any other of its activities. This has included consultation visits to State Universities and other educational institutions, with a view to organizing and standardizing post-graduate courses in public health nursing. In this way the experience of one has been made available to all, along the lines of entrance requirements, curriculum content, field work, etc.

The Organization is not only interested in public health nursing education. One of its secretaries has been loaned

to the Central Council on Nursing Education to organize and direct a campaign for recruiting student nurses which has been doing admirable work, with gratifying results, since April, 1920.

Serves Through Library Centers

Intimately related to the work of the Educational Secretary, and contributing to that of all the Secretaries, is the library. When this department was organized, it was planned that a good collection of current pamphlets and books should be maintained within the New York offices, but in addition that there should be projected into the states some form of library extension work that should represent the National Organization for Public Health Nursing. To this end, state library centers have been established through local library agencies to which nurses may write for both books and pamphlets on community health. Briefly, the main activities of the library department may be described as a pamphlet lending service through the Package Library; an extension service through State Library Centers; a reference service through a special Reference Collection of both pamphlets and books; an advisory service through a section of Book Reviews and Digests contributed monthly to the *Public Health Nurse* magazine.

The official magazine of the Organization, the *Public Health Nurse*, which is now a monthly issue, is justly called a current textbook on public health nursing. It is included with membership benefits. In collaboration with one of the secretaries, it edits a department on nursing in MODERN MEDICINE. The editorial staff is responsible for calling into existence a modest body of literature on public health nursing which was literally non-existent ten years ago.

"Public Health Nursing," by Mary S. Gardner, has, since its publication in 1916, been generally accepted as an authoritative presentation of the subject. A series of textbooks in special phases of public health nursing, under the editorship of Miss Gardner, are now being published by the Macmillan Company.

A unique enterprise which engaged almost the entire time of one secretary and four to six field nurses during 1918 and part of 1919 was three county demonstrations designed to show the value of public health nursing as a means of maternal and infant conservation. These were done under contract with the Federal Children's Bureau and will be reported by the Bureau in due time. The counties were selected with a view to giving wide variation of conditions, methods, and experience. They were Morgan County, Ill., having an absentee owner and Portuguese tenant farmer population; St. Mary's Parish, La., with a large negro population and the negro midwife problem; and Fremont County, Wyo., in which the Wind River Indian Reservation constitutes the larger portion of the population and which embraces two tribes, the Arapahoes and the Schoehenees.

The Indian Commission and the United States Public Health Service have also been interested in this latter.

War and Foreign Service

The War Service conducted by the Organization is worthy of special mention.

It was responsible for securing a special enrollment of public health nurses in order to reserve them for work in the sanitary zones, in reconstruction work in foreign countries, and to assist in preserving community health regulations and in furnishing nursing care at home, where medical and nursing forces were seriously depleted.

Its Associate Secretary served as Organizer and Di-

rector of Public Health Nursing in the Sanitary Zones under the United States Public Health Service. Its executive secretary acted as secretary of the three Committees on Nursing of the Council of National Defense.

It secured a large share of a special war service budget for these committees and contributed an extensive publicity program designed to greatly increase the number of candidates for nursing schools.

It suggested to the Red Cross the scholarship fund of \$150,000 for nurses returning from military duty, which has served a double purpose of providing for nurses who had surrendered their previous positions, and increasing the supply of qualified public health nurses to meet an enormously increased demand.

It secured the preparation and circularization of a special series of lectures on Venereal Diseases for Public Health Nurses and for senior students.

The Organization receives many calls from foreign nations, such, for example, as St. John's in the Wilderness, Alaska; Massachusetts-Halifax Health Commission, Canada; Victorian Order of Nurses, Canada; Peking Union Medical College, China; Maison de Sarte Hospital, France; Women's Christian Temperance Union, India; Inspector d'Hygiene of Gant, Belgium. Notable among these has been a call from Mrs. Mary Breckenridge, nurse in charge of public health nursing under the American Committee for the Devastated Regions of France to supply her with all possible current reports, pamphlets and leaflets on public health nursing, and to send her catalogues and announcements of post-graduate courses in public health nursing, and of a selected list of schools of nursing. All of this she needs to meet the awakening interest of French citizens in the American system of graduate nursing.

Its History Summarized*

The history of the Organization may be briefly summarized somewhat as follows:

From 1912 to 1916 it was frankly propagandist and opportunist in character, aside from the publication of its magazine, then a quarterly. The major portion of its secretary's time was spent in travel, her work being composed largely of consultations and public speaking. Its standard making work grew steadily through its various avenues of interpretation, chiefly in stating minimum requirements for public health nursing as expressed in qualifications for appointments to local positions and for membership in the national body, and in advice and information regarding rules and regulations governing the organization, administration and practice of public health nursing. The growth of its influence was reflected in the constant increase in its membership and in the formation of state organizations.

New phases developed from 1916 to 1919. By 1916, the demand for public health nurses had far exceeded the supply of women qualified either by experience or special training, and the public had begun to grow intolerant of unprepared nurses. The problem was obviously to increase the supply. Hence the Organization turned its primary attention to the work of stimulating the development of post-graduate courses in public health nursing; and in encouraging the introduction of elementary instruction in public health nursing in qualified training schools for nurses through carefully arranged affiliations with visiting nurse associations. It also secured scholarship funds in several states and one reserved exclusively for women who wish to prepare themselves as teachers of public health nursing.

It recognized the desirability of stimulating appropri-

ate legislation in behalf of public health nursing, and prepared two bills suitable for adaptation to the needs of the various states. These looked toward the appropriation of public funds for public health nursing, and toward the creation of divisions or bureaus of public health nursing within state departments of health with qualified public health nurses as chiefs of said divisions or bureaus.

During this period the Organization increased its staff and its budget threefold and opened branch offices in Washington and Chicago, the former only for the period of the war. By the middle of 1919 it had become necessary to departmentalize its work and appoint secretaries in charge of each department. It also arranged to open two more branch offices in the far West and South but was later obliged to postpone these projects.

A new era opened in 1920. The Red Cross peace program had, by this time, precluded all need for further propaganda service, but had built up an unprecedented need for serious advisory and educational and research work. Hence the officers of the Organization resolved to confine their activities very largely to the field of "consulting engineers" or expert consultants.

Conspicuous among the plans for 1920 was that of stimulating the organization of state committees on public health nursing composed of representatives of all state agencies engaged in or actively supporting public health nursing. The purpose of such committees was to mobilize public opinion in favor of wise standards of public health nursing; and to support state departments of health and other state agencies in securing appropriations and legislation when necessary; and to recruit larger numbers of public health nurses and of students for schools of nursing. In short, the aim of these committees is to mobilize a great body of "Friends of Public Health Nursing," as those citizens have recently been called, who are interested to promote this form of public service.

Indicates Research Activities

Public Health Nursing is still in the making. A great amount of serious study is needed before it can be adequately standardized. Eight years of constant application to the question have only served to prove its value and to point out its problems. It would be logical and is much to be desired that the National Organization for Public Health Nursing should now undertake many practical studies such as "Standardized units of work per nursing visit," "Standard forms for case records, statistical reports, financial statements," "Standard methods of organizing county units of work," "Minimum requirements of educational courses," and various statistical studies; and to prepare a handbook for speakers and many brief pamphlets on practical subjects. It is to be hoped that these urgently needed aids to local work and steps toward standardization may be promptly undertaken and that they may be done with the same scientific thoroughness that has characterized the recent study of public health nursing education conducted by the special committee under the direction of Miss Goldmark and Miss Anne Hervey Strong, and financed by the Rockefeller Foundation.

The Organization's history has been one of modest though creditable achievement. It has afforded a medium of exchange, a clearing house of information and interpretation; it has made public health nurses and public health nursing associations vocal. It should and, we believe, will press on to a future of larger service along these lines and help to mobilize and crystallize an intelligent public opinion, strong enough and appreciative enough to insure right standards and adequate appropria-

tions and to guarantee nursing care and oversight to all families at all time—and in fact to insure it as a state and national institution.

Professor C.-E. A. Winslow, chairman of the Advisory Committee of the National Organization for Public Health Nursing, and one of the best known sanitarians in this country, says:

"I consider that the National Organization has rendered and is rendering, and must continue to render, an abso-

lutely invaluable service in guiding and coordinating the development of the new profession of public health nursing. I know of no other social development comparable in magnitude with the growth of public health nursing, and your Organization—our Organization, I may say as a newly elected director—is the one agency which can furnish the inspiration and the counsel and the organizing and correlating power to keep the growth along sound and progressive lines."

CAMP ROOSEVELT AS A BOY BUILDER

BY LILLIAN EWERTSEN, DEPARTMENT OF EDUCATION, CHICAGO, ILL.

THE problem of education as a whole embraces three collateral branches—intellectual, physical and moral training. Education has the thoroughly practical end in view of rendering a man fully capable and efficient in the performance of all practical duties. Physical education is not to be thought of as something separate and apart from this scheme as a whole. Mental training is important, but no more and no less so than adequate physical development, from which it cannot be divorced.

Welton has said, "the function of the mind is rationally to control our actions in the world around us, while the body is the instrument by which the mind is brought into relation with external things." In order, then, that the body may be the effectual instrument for which it is intended, it must be sound and it must be trained to respond promptly and skilfully, with senses and muscular response in harmony.

Sound Physique, Sound Morals

Captain F. L. Beals, commandant of the camp, has made it his life study to achieve the maximum amount of help for the adolescent boy.

Before education can be effective, it must have a practical underlying purpose. In the case of education in its broader sense, this may be readily recognized. The practical application of this theory of education is more important than ever before—and the returns are readily recognizable.

While physical education has the same practical value, as a part of general education, its returns are not so readily appreciated by the uninformed. In order to give it force and make it effectual, it must have a deep and definite purpose.

Our future as a nation calls for stout hearts, clear heads, and vigorous manhood. Every young man entering upon life's tasks must possess these qualities if he is to succeed as an individual. If these qualities are cultivated in the individual, our country will be composed of stout hearts, clear heads, and the vigorous manhood which will insure a rational and vigorous race.

Every young American of today must be made ready for any undertaking which may require of him courage and endurance. The Chicago high schools, twenty-three in number, are exerting every effort to bring about these results through the Department of Physical Education

and its Junior Reserve Officers' Training Corps. Under Captain F. L. Beals of the United States Army, and his one hundred and fifty assistants, these two departments are laboring to develop better physical and moral types in these future American citizens. It is recognized that much of the good accomplished during the school year is lost during the long, idle summer vacation. Captain Beals has long felt that if these idle summer months could be put to some useful purpose, much good would redound to the individual and to the country at large. To be effective, a plan for accomplishing this would need to bring together a large number of boys from all walks of life for a common purpose; and, to secure the best results, would require them to be placed on terms of equality, both as to their daily modes of life and their clothing, in a place out in the open, under canvas, under a military and physical régime fitted to their needs. This plan was placed before leading business and professional men in Chicago, who endorsed it and agreed to furnish the necessary finances.

Thus grew the Camp Roosevelt Association, which founded Camp Roosevelt, the National Boys' Training Camp. The Board of Education of Chicago sponsored the camp, and the War Department of the United States Government supplied the necessary equipment and detailed specially selected officers and non-commissioned officers of the Army as instructors. For boys desiring to make up high school subjects, a summer high school was opened and selected teachers from the Chicago high schools were sent to camp.

Training Through Play

Camp Roosevelt has been described as the finest boys'

Major General Leonard Wood, pinning a medal on a boy during his recent tour of inspection at Camp Roosevelt. The War Department, after two tours of inspection, has stamped the work with full approval. A good physique is an achievement, not a chance product.

All activities have a proper objective, providing the incentive of interest and competition along with recreation in order to develop necessary coordinations.

playground in the country. It is located five miles south of Muskegon, Mich., in a beautiful valley surrounded by wooded hills, bounded on one side by Lake Michigan and on another by Lake Mona. The camp is so located as to give a maximum of recreation and enjoyment. It is sufficiently near water so that swimming may be indulged in freely; at the same time it is sufficiently far removed to insure safety. Its broad plains are ideal for drills, maneuvers, and athletics. The wooded hills by which it is surrounded constitute the necessary setting for such an enterprise. The natural wonders of the site of the camp alone make it a haven of joy to the boy.

It is interesting to note that the War Department has adopted the Camp Roosevelt plan as a national policy, with the purpose of establishing three or four more camps similar to Camp Roosevelt, the action being taken after two tours of inspection by representatives of the War Department to determine the status of the work carried on.

The daily program at camp includes military instruction, physical exercises, basketball, baseball, swimming, target practice, and all of the outdoor sports indulged in by the American boy. Week-end hikes to nearby lakes are featured. The evening entertainment includes movies, stunt nights by the companies, lectures by well known business men, campfires and programs arranged by the Young Men's Christian Association and the Knights of

We are only beginning to realize that it is through play activities, freely indulged in before we are muscle bound, that adaptability and accuracy are rendered habitual. The incidental "fun" registers this hard work as a fully harmonious reaction.

Columbus workers of the camp. The Scoutcraft Division conforms to a separate schedule especially adapted to the younger boys, ranging in ages from twelve to fourteen.

The American Red Cross maintains a unit at the camp, comprising three physicians and a Red Cross nurse. They care for the sick patients, administer first aid, safeguard the sanitation of the camp, and at the same time give to all of the boys enrolled a thorough course in first aid. Each boy must pass a test before leaving camp and, when he has successfully completed his work, he receives a first aid certificate for the work accomplished.

Captain Beals, commandant of the camp, has dedicated his life to boy building. Captain Beals' stock in trade is boys. His life interest is boys, and his ultimate aim is to so mold the growing boy of today that he will develop into the very finest specimen of clean, wholesome American citizen. As an officer of the United States Army he grasped the greatness of the health building work that had been accomplished at the training camps throughout the country during the World War. He sought long for ways and means by which to inculcate it into his work, so that the maximum amount of good could be wrought for the adolescent boy. The culmination of many months of strenuous, concentrated thought and labor is this tremendous camp for boys from all parts of the country.

The camp is a splendid force in Americanization, and in building up a democratic spirit among the boys. This is a vital factor, one of prime importance in the business of boy building. Parents of growing boys, and all who are interested in boyhood, should interest themselves in this project, and support to the fullest extent the Camp Roosevelt plan.

IMMUNITY TO YELLOW FEVER

A new factor in yellow fever control has been introduced through the possibility of making a person immune to yellow fever by vaccination. Heretofore, work in yellow fever control has been entirely confined to the prevention of infection by controlling breeding places of the mosquito which carries the yellow fever germ. The isolation of the yellow fever organism, however, and the discovery of Dr. Hideyo Noguchi, at the Rockefeller Institute for Research, has made possible the development of a serum and a vaccine which promises immunity against contracting the disease.

Already vaccination against yellow fever of people going to tropical countries is being made in New York. This work is being done at the Broad Street Hospital with vaccine furnished by the Rockefeller Institute.

The first shipment of vaccine for yellow fever from the Rockefeller Institute to tropical countries was made a year ago, when three hundred bottles were sent to Mexico. Other shipments have been made since then, the latest November 10. All vaccine supplied to Mexico is sent to the Mexican Department of Health, which arranges for its distribution. The Central American countries are so well convinced of the efficacy of Dr. Noguchi's vaccine that they are permitting travel without quarantine detention of those who have been successfully vaccinated.

REPORT ON RUSSIAN REFUGEES

The American Red Cross at Paris has issued a report which constitutes the first estimate of the distribution of the Russian refugees who have invaded every country in Europe during the past two years. Their present number is estimated at one million persons outside of Poland, where there are probably another million.

DIPHTHERIA BACILLUS CARRIERS

A VERY important study of the diphtheria bacillus carrier has been undertaken at the Johns Hopkins Hospital in the past few years. Some of the results have been previously reported, but recently Gelien, Moss, and Guthrie¹ have contributed two articles of great scientific importance. Their animal experiments on rabbits, guinea pigs, and cats on the effect of diphtheria antitoxin in preventing the lodgment and growth of the diphtheria bacillus in the nasal passages of these animals warrant certain conclusions, among which may be summarized: (1) The production of infection with the diphtheria bacillus was inconstant even when the organisms were introduced directly into the nose; (2) when infected, the duration was short; and (3) the occurrence of the infection was entirely unaffected by previous administration of antitoxin. Although one must hesitate always in drawing too sweeping conclusions from animal experiments, these certainly offer affirmative evidence of the well established clinical fact that antitoxin has no effect on the diphtheria carrier.

In a second communication² the same authors devote their attention to a study of the diphtheria carrier. In their new study they extended the scope of the previous investigation. The information obtained is too detailed and too important to permit easy comment, but certain conclusions can be evaluated. For instance, 10 per cent of a certain group of school children in Baltimore in February, 1912, showed Bacillus diphtheria and the number of children who yielded positive cultures at one or other

examination was 18 per cent. There is no apparent direct relationship between pathological throat conditions and the incidence of the bacilli. Eleven per cent of the cultures were found to be virulent. Temperature elevations in the individual child had no direct bearing on the culture.

It was also shown that Bacillus diphtheria found in the throats in various school children varied from time to time, being present at one examination and absent at another. It was also found that at one examination the cultures might be virulent and at another avirulent.

From the standards of public health the relation of the bacillus carriers to the community is of the greatest importance and this point was carefully investigated by the authors practically with negative results; that is, the carriers were not exposed to clinical diphtheria and no clinical diphtheria followed in the wake of the carrier. The question might be raised as to whether the authors were dealing with true Bacillus diphtheria. This point is thoroughly discussed in the body of the article. On the whole, as a summary, it seems to us that this article should be studied by every one interested in hospitals, public health, or a general community health.

VACCINATION WITH TUBERCLE BACILLI

CALMETTE and Guérin¹ published the results of their investigation before they had originally intended. Their work, which had reached a considerable degree of development, was interrupted by the war, and they have been unable to resume it.

They have been able to obtain a strain of attenuated

bovine tubercle bacilli by cultivating this organism over a period of twelve and one-half years on medicine containing bile and glycerin. It is evidently the bile which has produced this attenuation of the organism. They believe that this attenuation has become a permanent characteristic of this strain of bovine tubercle bacilli. They have proved it to be avirulent for cattle, monkeys, and guinea pigs, and make the statement that an intravenous injection of 44,000 of these tubercle bacilli proved non-pathogenic for man.

These investigators demonstrated in the laboratory that the injection of large intravenous doses into animals caused the animals to develop resistance against subsequent lethal doses of virulent tubercle bacilli. They decided that the supreme test of the value of a vaccine of these avirulent tubercle bacilli would be the ability to protect cattle from infection when these animals were continuously exposed to infection by contact with other tuberculous cattle. The material published consists of a single series of experiments of this type. Ten calves were kept in a specially constructed stable for two and one-half years with a number of cows which were proved to be tuberculous. Four of these calves served as controls. The other six were vaccinated intravenously with large doses of living avirulent tubercle bacilli. Three were injected with a single dose of 880,000 tubercle bacilli—one with two doses, and two with three doses. Three out of the four controls reacted to tuberculin before they were killed, and showed tuberculous lesions at autopsy. The fourth one was adjudged by the investigators to be naturally immune. One of the three which received only one dose of vaccine showed no tuberculin reaction and no tuberculosis at autopsy. The calf that received two doses of vaccine showed no reaction to tuberculin and no tuberculosis. Both the calves which received three injections of vaccine showed no reaction to tuberculin and no tuberculosis. The authors conclude that they have demonstrated the protective action of intravenous injection with the living avirulent tubercle bacilli used by them. They believe that single doses cause resistance to the infection of tuberculosis for a period of only about eighteen months. They believe that longer periods of immunity, possibly permanent immunity, can be developed in animals by several intravenous inoculations, or what might possibly be better still, by inoculation once a year.

This work must be considered as of supreme importance, as it confirms the conclusions arrived at from all recent investigations as to the manner in which immunity to tuberculosis may be developed. None of the various types of tuberculin or products of tubercle bacilli have experimentally conferred immunity on animals. Therapy with these various non-living products of tubercle bacilli also yielded no results. Investigators in the field of tuberculosis have long realized that the only chance of combating tuberculosis lay in the development of a living strain of tubercle bacilli which would stimulate resistance, and yet not infect or be dangerous to the patient or animal.

So many false hopes have been raised by many previous investigations of tuberculosis that one is naturally guarded in accepting work which now appears. This investigation of Calmette and Guérin,* however, is an extremely careful, painstaking research and carries with it very conservative claims by these two workers. The authority of Calmette adds great weight to this research,

which should, therefore, be received with an open mind as well as with a great desire for further facts and for a trial of the original experiments in a large series of animals. It gives one renewed hope that, in spite of the previous disasters, possibly something to alleviate or prevent tuberculosis in man has been discovered. W. T.

DEFORMITY FOLLOWING BURNS

HARRIGAN and Boorstein¹ call attention to the need of immediate treatment to prevent deformity following burns. This, as they remark, is something all physicians know but are too prone to forget. With the very first dressing steps are taken to keep the limbs, neck, jaws, or other members in such positions that when healing has occurred the resulting scar tissue will not have caused anatomical deformity. For example, in extensive burns of the neck, after having applied to the burn the paraffin, picric acid, or whatever dressing may be used, instead of covering with the usual bandage, the authors apply a high felt collar which holds the head erect, with the chin tilted upwards. This collar is closed with clips or is sewed on, is as easily removed at subsequent dressings as would be a bandage, and keeps the head and neck in good position. Should a tendency develop in spite of this to pull the head to one side or the other, counter pressure is made by heightening or padding the collar on the wounded side. Burns of the anterior surface at the elbow are treated with the forearm extended from the time of the first dressing. In similar way are burns of other parts of the body cared for, the part held in normal position or in that position which the occurrence of a strong cicatrix might prevent. The authors, quite naturally, have found that by conscientiously carrying out this line of treatment, the results obtained are far above the average, in fact they say, "... we have noted, to our great satisfaction, that no contractures have developed."

R. B. B.

DR. OTTO L. SCHMIDT HONORED

ON DECEMBER 21, 1920, a number of physicians, clergymen, jurists, and other prominent citizens of Illinois gathered to express their appreciation of Dr. Otto L. Schmidt of Chicago, this formal expression of appreciation being occasioned by the completion of the work of the Illinois Centennial Committee, the purpose of which was to collect historical material pertaining to the state of Illinois. Dr. Schmidt was commended as a physician, as an historian, and as a citizen.

Very seldom does such a signal honor come to a man during his lifetime, but Dr. Schmidt merits it in full measure. He is one of the most prominent physicians of Chicago; he has always practiced scientific medicine. He was one of the few in this country who made use of x-ray immediately after its introduction, and he has always combined clinical and laboratory methods. He is generally known in Chicago as the "poor man's doctor," following in this respect the example set by his father, Ernest Schmidt, a prominent physician and philosopher of the last century.

In addition to his medical work, Dr. Schmidt has been interested in the study of history, particularly in the history of Illinois. He has gathered in a scientific manner many hitherto unavailable data which were scattered in books and in journals, thus making possible a consecutive and reliable history of the state of Illinois.

¹ 1. Harrigan, Anthony H., and Boorstein, Samuel W.: *Orthopedic Treatment of Burns*, Ann. Surg., 1920, Lxxii, No. 5.

*Since this editorial was written reports in the daily press indicate that an extensive experiment will be performed with this vaccine of avirulent, living tubercle bacilli. It is stated that the French Government has put a small island off the coast of Africa at the disposal of these investigators. Funds are being raised and monkeys and the higher apes will be secured for the investigation. The result of this research will be awaited with great interest.

CHOLECYSTITIS, CHOLELITHIASIS AND PANCREATITIS

FOR a number of years cholecystectomy rather than cholecystostomy has been the surgical procedure of choice in diseases of the gall bladder. The greater frequency of this operation has given increased opportunity to study the pathology of the gall bladder, especially the pathology of early lesions.

McCarthy¹ has recently set down a description of early changes in gall bladders removed for stones, in which the mucosa appeared normal to the naked eye, but, microscopically, showed very evident lesions, appearing as congestion and edema of the villi, transforming their normal thin, tentacular appearance to bulbous, sometimes cystic swellings. Often there is slight lymphocytic infiltration of the villi. Coincidentally there is a round cell infiltration in the submucosa and the mucosa muscularis, this condition being followed by fibrosis: *i. e.*, these gall bladders show the evidences of mild chronic inflammation.

Proof of Infectious Origin

Strawberry gall bladder was first described by Moynihan² as "a disease of the gall bladder requiring cholecystectomy," and characterized by thick, tenacious, tarry bile, with the mucosa "dusted with fine stones fitting snugly into pits in the mucous membrane."

This condition is encountered more frequently since cholecystectomy is the operation of choice, being exhibited in 7.5 per cent of cases in 1912³ and in 19 per cent in 1917. The yellowish plaques are not stones, but lipoids beneath the epithelial surface. In the above group of very early lesions there is often observed microscopically a deposit of fine, lipoid granules in the mucosa and submucosa. Generally there are fine dots—identified by using stains for fats—in or just beneath the lining cell layer of the mucosa, but sometimes there are large spheroidal cells filled with lipoid masses deeper down in the mucosa and in the submucosa.

These changes should relegate as passé the old dictum that gall stones are frequently found in normal gall bladders, and the uniformity with which mild chronic infection can be demonstrated has an important bearing on Rosenow's well known ideas regarding infection as the agent responsible for gall stones. Rosenow⁴ cultured streptococci, and occasionally a colon bacillus, from sterily macerated gall bladders. These organisms, when injected intravenously into rabbits, produced cholecystitis, frequently with the formation of stones. The stones so produced always had a bacterial nucleus. In one case stones were found ten days after injection, and in their centers were virulent Streptococci. The Streptococcus was the chief trouble maker, for the colon cultures did not give nearly so uniform results, and one case of cholelithiasis following typhoid was found to be due to the Streptococcus. Intravenous injection of the cultures alone would reproduce the disease; injection into the portal system or directly into the gall bladder gave no results. This would indicate that cholecystitis is a blood borne infection; hence the significance of lymphocytic infiltration and fibrosis in the submucosa of gall bladders containing stones, but not suspected macroscopically as being abnormal. According to Rosenow's work, there has been enough inflammation to initiate the precipitation of stones.

Infection, however, may be considered as only part of

the story of gall stone formation. Four pure cholesterol stones in Rosenow's series contained no bacteria. Recently Rothschild,⁵ Wilensky,⁶ and Rosenthal⁷ have studied the metabolism of cholesterol, to determine the rôle which states of cholesterol supersaturation play upon its precipitation as gall stones.

The Cholesterol Content

The content of cholesterol in the blood varies directly with the diet. Herbivora, whose diet is poor in lipoids, have a low blood cholesterol index, and a hypercholesterinemia can be produced in these animals by feeding lipoids or a fat rich diet. In direct relation with the amount of cholesterol in the blood is the amount present in the bile. According to Rothschild, cholesterol supersaturation in the blood will be followed by supersaturation in the bile, and under certain conditions by precipitation as stones in the gall bladder. The commonest occurrence, clinically, of hypercholesterinemia is in pregnancy and during the puerperium. The frequency of initial gall stone attacks in the later months of pregnancy or shortly thereafter is elementary clinical knowledge. Natives of China, Java, India, whose diet resembles that of herbivora, and who have low blood cholesterol, have a low incidence of cholelithiasis. Gall stones are most frequent among the people of the western world, whose diet is most omnivorous, and they are four times as frequent in women as in men, this latter fact due solely to the hypercholesterinemia of pregnancy. In men "infection dominates the field; cholecystitis without stones is found more often, and stone formation is secondary." The finding of gall stones *post mortem*, with no history of symptoms, is explained by Rothschild as being the precipitation from a period of hypercholesterinemia, perhaps without the recurrence of this condition and without the lodgment of a calculus in the cystic duct or the production of inflammation.

However, granted that stones do form without inflammation and, also, that inflammation undoubtedly will induce gall stone formation, the enigma still remains as to which is the preponderant factor in the majority of cases of cholelithiasis. One explanation would be much more rational than two separate and distinct ones. The ultimate solution may be that the mechanism by which cholesterol is held in solution in the gall bladder is very sensitive. It is known that increase of bile salts may enable the bile to hold in solution an extraordinary amount of cholesterol, and that inflammation of the gall bladder precipitates the mucin and allows for a greater concentration of the bile salts.⁸ Perhaps mild degrees of bacterial inflammation may alter the physical characteristics of the bile sufficiently to cause precipitation of the cholesterol. This takes place more easily when the blood, and consequently the bile, is in a state of cholesterol supersaturation.

In this connection Meltzer⁹ has emphasized the fact that the physiological stagnation of the bile in the gall bladder of itself predisposes to calculi formation.

Gall Stones With Pancreatitis

When Opie¹⁰ showed in 1901 that injection of bile into the pancreatic duct would cause pancreatic necrosis, and later demonstrated at an autopsy at Johns Hopkins that a small stone impacted in the papilla of Vater could set

up a fatal pancreatitis, he furnished an apparently satisfactory explanation of what was then a very obscure condition. Subsequent clinical reports confirmed the association of gall stone disease with pancreatitis, but there has always been the stumbling block that frequent cases of pancreatitis show no stone in the ampulla, and it has become increasingly evident that although there is usually some associated inflammation of the gall tracts, pancreatitis does occur without gall stones, a condition reported in 45 per cent of Deaver's¹¹ cases. Also, an occasional case of pancreatitis is met with following peptic ulcer. These facts have led to the assumption that in the absence of a stone in the ampulla, a plug of infected mucus had dammed back the bile, and have led Deaver to assert that pancreatitis is a retrograde infection through the lymph channels, the enlarged lymph nodes at the head of the pancreas seemingly supporting this.

Archibald¹² has recently offered another and very logical explanation. As a rule, in the lymphatic system, infection travels with the course of the lymph stream, and not in the opposite direction against the current, the so-called retrograde infection. Thus, infection travels up the arm to the axillary glands, or from the breast to the axilla, but not *vice versa*, from the axilla to the arm or breast. Carcinoma cells may mechanically grow in a retrograde fashion along the lymphatics, but, for the average inflammation, the lymph glands draining an organ act as a barrier against the spread of infection toward that organ. The glands at the head of the pancreas drain the pancreas; the normal lymph stream through them is from that organ. Consequently, their enlargement should denote a lesion which is primary in the pancreas rather than their being the means of bringing infection to the pancreas. Also, the diseases of the pancreas are hemorrhagic necrosis, cyst formation, induration, etc.—abscesses or other evidence of infection being relatively uncommon. It follows that an infected plug of mucus in the ampulla is not the mechanism which dams back the bile.

Oddi's sphincter is a bit of smooth muscle surrounding the common duct just beneath the duodenal mucosa. It is capable of resisting 600-700 mm. water, two or three times the normal secretory pressure of the bile in the liver—which is 230 mm. It was accurately described by the Italian physiologist Oddi in 1887; but, although somewhat known to physiologists, it had never been given any clinical importance; in fact, when Archibald¹² first postulated it as the mechanism concerned in the production of pancreatitis, he was unaware of Oddi's work. This sphincter can be put into spasm by mechanical irritation of the duodenal mucosa, by the application of dilute HCl to the stomach or duodenum, or by stimulating the vagus. Archibald thought that the physiological contraction of this sphincter was enough to cause bile to run into the pancreas. By running bile into the gall bladder under pressure greater than the normal biliary secretory pressure, but not great enough to force the sphincter and let it run into the duodenum, he produced an acute hemorrhagic pancreatitis in his first cat, fulminating enough to kill it in twenty minutes. By regulating the pressure and the amount, varying degrees of pancreatitis could be produced, from the above fatal type to benign hyaline scars. Infected bile produced pancreatitis more readily than non-infected, and bile salts were much more destructive to the pancreas than bile. The bacteria prob-

ably acted mechanically by precipitating the mucin of the bile, as older experiments showed that bile deprived of its mucin caused pancreatitis more readily.¹³ The pancreatic necrosis is a true tissue death, without the aids of autolytic ferments, trypsinogen, enterokinase, or inflammatory exudates—all of which have been held responsible for pancreatic necrosis.

In ordinary life, bile must enter the pancreas fairly frequently. If only in a small quantity, it leads to a bit of hyaline degeneration; such plaques are frequently found at autopsy without any assignable explanation. Clinically, the attack which produced this localized necrosis may have been some vague undiagnosed upper abdominal distress, coming on perhaps two or three hours after a full meal. At this time the secretory pressure of the bile is at its height, and acidity may be forcibly contracting the sphincter. Hyperacidity, reflexly contracting the sphincter, predisposes to pancreatitis; in fact, many cases of pancreatitis have a history of hyperacidity.

If the destruction is greater than the above localized plaques, the indurated, enlarged, firm pancreas, which gets well by drainage, is produced; and, if the necrosis is fulminating, cyst, hemorrhage, abscess, or acute death ensues.

Post-operative drainage through the common or cystic duct should be prolonged—as much as three months for the average moderately severe case. Some recent views,¹⁴ never very popular, that drainage should be through the anterior abdomen, with multiple incisions into the pancreas to anticipate inflammation, have, of course, no *raison d'être*, excepting this work. Cholecystectomy and drainage of the common duct is better than cholecystostomy. The reason is that after cholecystectomy the extrahepatic ducts dilate.¹⁵ The biliary secretory pressure, instead of forcing bile into the gall bladder, dams it back behind the sphincter. Gradually the sphincter loses its tonus, until it can withstand only a small fraction of the biliary pressure, and then bile drains into the duodenum without hindrance. That cholecystectomy of itself cured pancreatitis, by in some way producing drainage, was a clinical observation before this mechanism was known.

HARRY SALTZSTEIN.

LIFE OF TRANSFUSED BLOOD CORPUSCLES

WHAT happens when we transfuse whole blood from a healthy individual into a sick or wounded person? Does the new blood act simply as a medium which dilutes the remaining blood and distends the arterial system, or does it take up the actual function of the blood and act as an oxygen carrier, and so forth?

If the former action takes place, then normal saline for a short time, and gum arabic solution for a longer time, ought to have all the advantages of a transfusion. The procedure is much simpler, no donors are required and the transfusion mixture can easily be accessible. If, however, the addition of whole blood has advantages other than simple mechanical ones, if the transfused blood, in adding a certain numbers of antibodies, also adds elements which contribute to the general metabolic process, then the question naturally arises, for how long a period will these elements function?

This question is answered in part by Ashby.¹ Working at the Mayo clinic, this author in a series of interesting experiments arrived at certain conclusions regarding the

life of the transfused red blood cell. It was shown that from 60 to 80 per cent of the transfused red blood cells remained in the circulation of the recipient for an average of thirty-one days; 40 to 50 per cent remained for an average of more than thirty-seven days.

These figures were arrived at in the following manner. It had been shown, in previous work by the same author, that mixed red cells of different groups could be separated *in vitro* almost quantitatively from one another, by means of serum which would agglutinate one set of corpuscles and leave the other free. When sera are used which are but slightly diluted, the agglutination of the red cells of the groups for which the sera contain agglutinins is almost complete. If, now, a given amount of Group IV blood—which serum agglutinates the red cells of all other groups, but naturally does not agglutinate the cells of its own group—is added, it will be found that the number of unagglutinated red cells increases in proportion to the amount of Group IV blood added.

The same holds true *in vivo*. Given a person in Group I, II, or III, it will be found that, when tested with Group IV serum, agglutination will be practically complete. If the same person be transfused with Group IV blood and, following this, another agglutination test be made, the number of unagglutinated red cells will have increased markedly. Various authors have evolved methods for determining the total blood volume, and by using these figures it is found that the number of unagglutinated red cells will vary rather accurately with the amount of dilution which has occurred. Ashby made the study with a group of patients suffering from anemia without idiopathic blood disease.

The decision as to whether saline solution, gum arabic solution or other synthetic fluids, or whole blood be used for transfusion, ought to be easier to make, knowing that in all probability more than 50 per cent of the transfused blood cells will remain in the circulation of the recipient for a longer period than thirty days. It would, however, be interesting if in some way it could be shown that these red cells not only remain in the blood stream but are alive and functioning.

HISTORY AND BIBLIOGRAPHY OF ANATOMIC ILLUSTRATION*

It is the irony of fate that an author should die before the publication of his masterpiece. This is what happened to Dr. Mortimer Frank—gentleman, physician, scholar, ophthalmologist, and medical historian. At the time of his death Dr. Frank apparently was in the full tide of his physical and mental powers. He was called suddenly, at the early age of forty-four years. Only the initiated, those who have followed the bypaths of medical history, such as the one explored by Dr. Frank, can appreciate our loss.

This book purports to be a translation of Choulant's "Geschichte und Bibliographie der anatomischen Abbildung nach ihrer Beziehung auf anatomische Wissenschaft und bildende Kunst," published at Leipzig in 1852. The work, however, is much more than a translation, for the original text of Choulant has grown, by the translator's notes and additions, from 203 to 435 pages.

The additions made by the translator are of great value. Since Choulant published his original work vast stores

of facts have been supplied by the researches of such writers as Baas, Pagel, Neuberger, von Töply, Holländer, Sudhoff, Garrison, Osler, and others. The notes which Choulant doubtless intended for use in a second edition have been incorporated in the volume and a life of Choulant has been supplied by the translator. A scholarly chapter on "Sculpture and Painting as Modes of Anatomical Illustration" has been written by Fielding H. Garrison and Edward C. Streeter. The work closes with an account of "Anatomical Illustration Since the Time of Choulant," from Garrison's fertile pen. Space allotted to this review does not permit a detailed account of the

JOHANN LUDWIG CHOULANT

"The history of a science is the palladium of its freedom; it prevents it from being tyrannized over by narrow, bigoted viewpoints."

contents of this work. It is not too much to say that its publication marks a milestone in the study of medical history among English-reading peoples.

A word as to the merits of the translation. Those of us who have waded through what Garrison calls "the prosy, sesquipedalian, sometimes obscure sentences of the original," will welcome this book. Dr. Frank has taken the long and involved sentences of Choulant, chopped them into smaller segments, clarified their meaning, and presented their truths to us with the verve and dash of a vivid and charming style.

Just as Vesalius said of his artist, Jan Stephan van Calcar, that he deserved to rank "with the divine and happy wits of Italy"; so may the reviewer be permitted to express a similar sentiment regarding the translator and elaborator of Choulant's classic.

Translated and edited with notes and biography by Mortimer Frank, B.S., M.D., with biographical sketch of the translator and two additional sections by Fielding H. Garrison and Edward C. Streeter. University of Chicago Press, Chicago, 1920.

PROGRESS IN PEDIATRICS—COLLECTIVE ABSTRACT*

DURING the war pediatric literature was almost at a standstill. Many of the pediatricians of this country and abroad left private and hospital practice to enter military service. Only the most pressing problems occupied the minds of those who remained at home, and the results of such researches as were made were not written. As to the work done abroad, especially in Germany and Austria, until very recently no report of it reached us. Now, however, with the end of the war, pediatricians are resuming activities, with the result that pediatric literature is returning to normal. Of the work done in Austria under the stress and strain of privation due to the food shortage, the work of von Pirquet¹ and his associates stands out pre-eminently. From them we have the latest word in infant feeding, although prediction cannot be made as to what success will be attained by other workers in the field with the new system of feeding Pirquet and his associates have inaugurated.

The New Nutritional Unit

In his new system of feeding, Pirquet substitutes the term *Nem* for the commonly used term, *calories*. Pirquet believes that the conception of calories is too vague and is not understood by the average physician. *Nem*, on the other hand, is a unit which is equivalent to 1 gram of mother's milk, consisting of 1.7 protein, 3.7 per cent fat, and 6.7 per cent sugar. All other foods are compared on the basis of 1 gram of mother's milk or *Nem* (*Nutritionis Elementum*).

Even more important than the new term, *Nem*, is the system developed by von Pirquet to figure out the individual food requirement of a child. Prior to this investigation the work of Heubner and Rubner had been the only basis of calculation of a child's food requirement. These workers determined by metabolic experiments that the food requirement of a child under six months is 100 calories per kilo bodyweight. Pirquet, on the other hand, believed that the determination of the fuel needs of child in a metabolism box cannot serve as a basis for the active child, and therefore looked for another standard, which he believes he found in the intestinal area. In order to figure out the daily requirements of food, Pirquet states that it is necessary to keep in mind the fact that there are minimum, optimum, and maximum food requirements.

The minimum requirement is the amount of food necessary to replace the wear and tear of the inner workings of the body, such as the work of the heart, of the respiratory apparatus, and the glands. The maximum requirement is the largest amount of food the stomach and bowels can take care of; in other words, the limit of tolerance. The optimum requirement is the amount of food necessary for a well functioning body to maintain health and to thrive.

For the maximum amount, 1 *Nem* is necessary for every cm² of intestinal surface, the intestinal surface being found by measuring the sitting height of the individual. For instance, the maximum of food in twenty-

four hours for an infant of 40 cm. sitting height is equal to 40², or 1,600 *Nem*. In a breast fed infant it equals 1,600 grams of mother's milk. In an older child the food is not milk, but the total amount is the equivalent of 1,600 grams of milk.

The minimum daily food is usually three-tenths of the maximum amount; hence an infant measuring 40 cm. sitting height requires 1,600x0.3 *Nem* as its minimum, or 480 *Nem*, that is, 480 grams of mother's milk. A given amount of food must be allowed for growth, one decinem being considered sufficient for that. One decinem is also allowed for fat deposit, so that we have in infants 3 decinem *siqua* for the minimum, 1 decinem for growth, and 1 or 2 decinem for fat, making a total of 5 or 6 decinem.

In the second half year, 1 decinem is added for muscular movements, making a total of 6 to 7 decinem. Assuming that the child at this age has a sitting height of 40 cm., it is to get 1,600x0.7 *Nem*, or 1,120 *Nem*. This can be given in the form of milk and cereals; for instance, the child may be given 5x160 grams, or 800 grams, of half milk with 68 grams of sugar. In addition to this, 160 grams of farina gruel can be given 2 times, which equals 320 *Nem*. This will make the total for the day 1,120 *Nem*.

Work Reported on Vitamines

Next in importance to Pirquet's system of feeding is the work done on vitamines. Daniels, Byfield, and Loughlin² report extensive work on antineuritic vitamine. They find that the addition of the antineuritic vitamine obtained from wheat embryo to the diet of babies furnishes an adequate number of calories to stimulate growth. The beneficial influence of adding a specially prepared vegetable soup in sufficient quantity as part diluent in the milk modifications for infants is apparently due to the presence of the antineuritis vitamine which it contains. Both the alcoholic soluble material of the dried soup vegetables and the water extract (soup) stimulated growth in the authors' experiments.

The fact that the artificially fed infant requires a larger amount of food than the breast fed infant appears to be due to the relative paucity of diluted cow's milk in the antineuritic vitamine. It is probable that failure to gain in infants and young children is often the result of an insufficient amount of the antineuritic vitamine in the food. The diets of the young, according to the authors, should be more carefully scrutinized with this in mind.

Hess and Unger³ have reached the conclusion that the danger to infants of a diet deficient in fat-soluble vitamine is slight, provided it includes sufficient calories, and otherwise is complete. Infants can maintain their health and vigor despite amounts of fat-soluble vitamine so small as rarely to be encountered. In spite, therefore, of the fact that this vitamine is not widely distributed in nature, a disorder that may be termed "fat-soluble deficiency"—marsasmus or xerophthalmia—is hardly to be apprehended from a clinical standpoint.

Revive Chemical Analysis

A new turn in infant feeding is the revival of chemical analysis of breast milk. Years ago physicians were in

*A two-part review, the first dealing with the problems of infant feeding, and the second, which will appear in the February issue of MODERN MEDICINE, dealing with the general phases of pediatrics.

the habit of testing mother's milk for the fat content in order to see whether the milk was too poor or too rich in fat. Of late the trend of opinion has been that all mother's milk is the same, that there is no such thing as bad breast milk, and that, therefore, the chemical examination of the milk is useless. It is therefore interesting to note the work done by Slawik.¹ He believes that abnormally high fat content of human milk is worthy of special observation as a cause in the nutritional disturbance of the nursling. To diagnose nutritional disturbance as such, because of an abnormal chemically composed milk, a lengthy and thorough examination of mother and infant is necessary, so that all other possible causes may be excluded. In any case, he says, one should never neglect to examine the mother's milk and its fat content in all chronic gastro-intestinal disturbances of nurslings with uncertain etiology.

Bacteria in Nutritional Disturbance

It is also interesting to note the return of some pediatricians to bacteriology as a basis for nutritional disturbance. As is well known, pediatricians have given up the theories of Escherich and his school regarding the rôle of the intestinal flora in diarrhea of infancy. The work of Porter, Morris and Meyer² is reviving the Escherich idea, these authors having found that children whose diet is well balanced and whose nutrition is normal have an intestinal flora consisting of fermentative and putrefactive types without preponderance of either. Children fed on large quantities of cow's milk have a more complex flora made up of various types, most of which are facultative putrefactors.

In children who suffer from certain of the types of alimentary intoxication with malnutrition, the intestinal flora depart in a uniform manner from the normal, this departure always being characterized by the establishment of bacteria, predominantly fermentative types, and a later swing to balance between the two types. Such changes in the intestinal flora can be brought about in the intestine of the human infant by withdrawing animal protein and persistently feeding large amounts (from two to four ounces daily) of lactose and other carbohydrates, the period necessary to produce this variation ranging from ten to forty days. While feeding acidophilus cultures has in a few cases aided a more rapid establishment of aciduric flora in the baby's intestine, this influence was not very great. The progressive cessation of the symptoms of intoxication and a return of toxemic patients to nutritional health coincides with the recognizable dominance of a fermentative flora. Lactose and dextrines are the carbohydrates most effective in encouraging the rapid establishment of a fermentative flora in the intestines of infants and children.

Feeding Atrophic Infants

Great interest was aroused by the work of Marriott,³ who used lactic acid milk in the feeding of atrophic infants. The author has fed undiluted lactic-acid milk containing amounts of fat up to the proportion contained

in whole milk, and has been convinced that the great majority of weak, athreptic infants tolerate extremely well undiluted whole lactic-acid milk in fairly large amounts—one-fifth of the body weight or more daily. Infants under two months of age he usually fed the lactic-acid milk somewhat diluted, but the evidence is not conclusive that such dilution is essential.

He also added carbohydrate in the form of commercial corn syrup to the whole lactic-acid milk fed to athreptic infants, and the results were good. There was little or no tendency to diarrhea, even when as much as 10 per cent of carbohydrate was added. The stools remained firm, formed, and pasty, averaging from one to three a day. In the case of some infants there seemed to be almost no limit to the amount of carbohydrate that could be added to such a milk mixture.⁴

In spite of the newer work, there are some pediatricians who claim to have attained success with the older methods of treatment, namely, withdrawal of food, purgation, and a gradual return to milk. Griffith⁵ believes that the most vital step in the treatment of summer diarrhea is the complete removal of food at the beginning of the attack. In addition to the removal of food, he advises the administration of a purgative, such as castor oil for young infants, and magnesia for young children. This advice is contrary to the opinion of many pediatricians, who claim that purgation is not only unnecessary but at times even harmful.

Success in Older Methods

A rather unique way of determining the digestion of certain food substances was adopted by Grulee⁶ in his use of the precipitin method—originally formulated by Hektoen—for the determination of the amount of digestion of egg albumin in infants. From a study by the precipitin methods of the stool of infants and children, he came to the conclusion that egg albumin is in nearly every instance completely broken down by the digestive processes in infants and children, and he believes that this holds good even for the newborn.

The alkaline reaction of food is claimed by Hess and Unger⁷ to be responsible for the development of scurvy. These authors believe that too little regard is paid to the deleterious effect of the alkalization of food for infants. If this is so, the addition of certain alkalis to many of the proprietary foods would prove harmful. Further investigation will demonstrate the value of this observation.

Orange juice as a laxative was thought to be too well established a fact to be disputed. Mothers and physicians alike have long had recourse to orange juice to combat the constipation of infants. It is, therefore, surprising to note the experience of Gerstenberg and Champion,⁸ who found in orange juice a constipating effect. They compared the action of orange juice with a 10 per cent sugar solution and found the latter to have a much greater laxative effect than the former. The authors conclude, therefore, that orange juice should be used only as an antiscorbutic or as a diuretic, but not as a laxative. It is possible, of course, that the infant on whom these authors experimented was the exception rather than the rule. One must keep in mind the fact that no two children react exactly alike to any article of food.

Community hygiene, properly incorporated in the school activities and school program, and properly and wisely administered and methodized, is a form of preparation for construction citizenship.—James H. Harris.

SINGLE TRACK MEDICAL EDUCATION

The recent centennial of the University of Cincinnati Medical School was made the occasion for an expression from Dr. William T. Sedgewick, professor of biology and public health, Massachusetts Institute of Technology, on the needs of modern medicine and the means of meeting those needs as supplied by the medical curriculum of today. It was no mere coincidence, said Dr. Sedgewick, which led in 1869 to the establishment of the first of our state boards of health, that of Massachusetts, and of the city Board of Health of Boston in 1872, almost contemporaneously with the first fruits of the labors of Pasteur, Lister, and Semmelweis.

The requirements of the field have grown far out of proportion to any measures taken to meet them. Today we have in every one of the forty-eight states a state department of public health, for the proper administration of which at least forty-eight experts in public health and sanitary science are needed, with two or three times as many more for field or laboratory work. The United States Public Health Service also requires scores of qualified public health officers, and finds great difficulty in obtaining them. Still others are needed by the Army and the Navy, while hundreds of American counties, cities, towns, and rural regions either already have, or should have, full time, trained health officers. Private health agencies also, such as the International Health Board of the Rockefeller Foundation, our numerous anti-tuberculosis societies, the Red Cross, and many others, are at present seriously handicapped in their beneficent undertakings by finding it almost impossible to fill the places which they have with competent, trained personnel. The field of industrial medicine and industrial hygiene is likewise calling loudly for trained workers, while school physicians who are really expert mental hygienists, social hygienists and dental hygienists are everywhere greatly needed. And yet, although these facts are patent, we do not find our medical schools, even those of the most modern type, giving much if any attention to the Macedonian cry of the hour for training in public health.

Medical schools, to meet modern conditions, says Dr. Sedgewick, should provide courses in medicine leading to two degrees, the courses diverging after the first two years, on the one hand to the degree of Doctor of Medicine and on the other to the degree of Doctor of Public Health. The fundamentals of anatomy, bacteriology, physiology, and pathology would be the same in both cases for the first two years. It is right to provide generously for curative medicine,—for surgery, for internal medicine, for obstetrics, for gynecology, for otology, for ophthalmology, etc. But that medical school which today fails to provide also liberal instruction in preventive medicine, in public health laboratory methods, in epidemiology; and in preventive sanitation such as the sanitation of water supplies and other branches of municipal sanitation; in preventive hygiene, such as mental, social, personal and health administration—is overlooking some of the most important aspects of preventive medicine and is sending out its graduates unprepared for some of the most serious problems that they will have to face in the immediate future. The census of 1920 shows that our country, lately rural, is rapidly becoming urban, and urbanization spells sanitation, for sanitary conditions largely control the health of the people.

Special schools of hygiene and public health which have sprung up here and there are utterly inadequate to meet the needs of the times and, if medical schools do not want the medical sciences administered by every conceivable substitute which can be picked up, they must meet

the situation by erecting a superstructure for public health training upon the same foundations which underlie medical training, replacing surgery, obstetrics, gynecology, materia medica, therapeutics, pharmacology, and other purely medical subjects by such subjects as will properly equip a modern public health officer.

DR. WINSLOW GOES TO GENEVA

Dr. C.-E. A. Winslow has been appointed to the directorship of the public health activities of the League of Red Cross Societies at Geneva, Switzerland.

Prof. C.-E. A. Winslow of the Yale School of Medicine, and editor of the public health department of *MODERN MEDICINE*, has been granted leave of absence from the Yale Medical School for the spring term, in order that he may assume the directorship of the public health activities of the League of Red Cross Societies at Geneva, Switzerland. Prof. Winslow will return for the fall term after October 1. The long and creditable connection of Dr. Winslow with public health matters peculiarly fit him for this larger field. Dr. Winslow has served in public capacity in sanitary bacteriology and sanitary biology; he was professor of sanitary biology of the Massachusetts Institute of Technology, 1905-1910; he has been curator of public health in the American Museum of History in New York since 1910. He was a member of the American Red Cross Mission to Russia, and in various capacities has rendered exceptional service in public health engineering. He has contributed largely to scientific literature on subjects in bacteriology of water, ice, and air; purification of sewage, and ventilation. Better choice could scarcely have been made for the responsible post which Dr. Winslow is assuming, and it is expected that this opportunity for extended contact in a greatly broadened field of health activity will be reflected editorially in the pages of *MODERN MEDICINE*.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

NEW OPPORTUNITIES IN 1921

THE year 1921 gives greater promise for the fuller understanding of the economic and social value in industrial medicine than any preceding year. Not a little part of this advance in knowledge should come from the fact that the American Association of Industrial Physicians and Surgeons now has an official journal in this department of MODERN MEDICINE.

By this arrangement the long needed opportunity will be available to the physicians in industry for a freer and constant discussion of their problems. Much good has come out of the four annual conferences that have occurred since the organization of our Association. Those industrial physicians who attended went back to their own fields stimulated to new energies and enhanced the value of their services to their particular corporations by incorporating into their work the ideas received from the other members of the conference.

Those members of the Association who did not attend, however, have had to wait almost a year before the proceedings of the annual conferences were finally placed into their hands. Much of the interest in the papers presented at the conference had by that time disappeared, and it is doubtful whether these proceedings were fully digested by the members at large.

The present arrangement, by which the papers and discussions of the annual conferences will appear in MODERN MEDICINE, will give new value to every contribution presented at the conference. All good suggestions can, therefore, be put into practice that much earlier by the readers of the journal.

Of far more importance than this, however, in the dissemination of our ideas, is the opportunity thus afforded for the publication of monthly reviews, news notes, new studies contributed by the membership, and monthly editorials furnished by the members of the Board of Directors, who will also determine the general policy of the Section on Health in Industry in MODERN MEDICINE.

In the last analysis, the officers of our Association, in selecting MODERN MEDICINE as our official journal, have but created an open forum for the membership at large. The success of this arrangement will necessarily, therefore, depend upon the interest of the members in contributing subjects and taking part in discussions thus

made possible. Your Board of Editors can only be held responsible for directing the proffered discussion into what they deem to be the most useful channels. It remains for the membership to bring forth the problems as a result of their own research into the industrial field.

Industrial medicine has stepped out of its swaddling clothes, and needs no longer justify its existence. The experience of the men in the field is rapidly developing a new concept as to the most practical and economic application of the principles of scientific medicine and surgery to the people at large. It is pointing out to the medical profession the place where its energies may best be applied to the problems of the prevention and the cure of disease with the maximum efficiency. It is furnishing the basis for entirely new lines of research as to the sources and control of disease, new lines of treatment, and disease prevalence. Above all these, stands out the fact that industrial medicine, particularly, provides the research worker with a most promising field in the matter of the earlier diagnosis of disease.

To those in the profession who are concerned with the teaching of the medical sciences, the new specialty of industrial medicine has much to offer. Close contact by them with the leaders in industrial medicine will point out to them the necessity of so adding to the present curricula that the new medico may reach his graduation day with a better appreciation of his social obligations toward the prevention of disease, a larger comprehension of the economic value of health, to say nothing of the livelihood offered in this new specialty.

The teaching profession may also learn from this source of research how the graduate in medicine may be prevailed upon to keep up his high standards of practice, while it will also learn the most direct method of intensively educating the public regarding health matters.

When the leaders in the medical profession, the molders of public opinion, the various Foundations that stand for medical advance, take time to bring together the wealth of material that already lies within the medical files of industry, a considerable change in our social concept of medicine will occur. With this realization will come a more efficient application of the science of medicine not only in industrial field, but in public, private, and hospital practices as well.

EDITOR.

OCCUPATIONAL HAZARDS AND DIAGNOSTIC SIGNS*

BY LOUIS I. DUBLIN, Ph.D., AND PHILIP LEIBOFF,† STATISTICAL DEPARTMENT, METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY

THE Statistical Bureau of the Metropolitan Life Insurance Company has compiled a little work, the purpose of which is to aid the medical examiners of the company in the field to recognize symptoms of disease of industrial origin. This pamphlet,¹ entitled "Occupation Hazards and Diagnostic Signs," lists the health hazards under the four principal heads of dust, heat, humidity, and poison. The last is subdivided to show twenty-four of the more common poisonous substances met with in the industries. Each of these health hazards is then related to the symptoms, condition, or disease which are to be looked for. Finally, there are given the industries, processes, and occupations where such hazards exist. This part of the compilation was based largely upon the classic work of Sommerfeld and Fisher, but it has been expanded to include the results of the observations of Doctors Hamilton, Hayhurst, Edsall, Thompson, Kober, Hanson, and others made since 1910, the year in which the list of industrial poisons by Sommerfeld and Fisher appeared.

The chief merit of our pamphlet consists in the presentation of a supplementary list of a large number of occupations in which hazardous conditions are usually found. The occupations are listed alphabetically, and after each is appended a code of letters and numbers which refer back to the previously mentioned hazards. Thus, the first occupation, "Acetylene Gas Makers," appears with the code D1, 21, 18, which indicates that such workers are exposed to the hazards of poisoning (D) from ammonia (1); sulphuretted hydrogen (21), and phosphorus (18); likewise, throughout the entire list of occupations. By this means, the general practitioner can readily determine whether the person examined is in fact suffering from the effect of his occupation; for, by turning to the particular occupation in the list, he learns what hazards exist and what symptoms and diagnostic signs to look for. His examination is in this way made more illuminating; for he can look for the definite signs of disease and these are more likely to be found and properly interpreted than if no such direction were given. Photographic reproductions of pages of this pamphlet are given in Figures 1 and 2 to illustrate the nature of the compilation and the readiness with which it can be applied. Physicians, not specialists in occupational hygiene, can thus learn to detect the effects of industry and, conversely, can eliminate the occupation as the cause when certain symptoms are observed which do not fit the usually observed effects of the occupation.

Its Usefulness Demonstrated

The pamphlet has been widely distributed among the more than six thousand medical examiners of the Metro-

politan Life Insurance Company. It has been well received by them and it has demonstrated its usefulness. The general practitioner and insurance examiner cannot be expected to know the hazards of industry and the indications of disease resulting from industrial exposure. This pamphlet apparently has served to overcome these limitations of knowledge and experience. It has also had the effect of interesting thousands of medical men in industrial hygiene; it has widened their horizon and has made them agents for the collection of industrial and hygienic information. As they are widely distributed over the United States and Canada, and operate especially among the industrial population, their opportunities for the collection of important data are many.

Figure 1.

ALPHABETICAL LIST OF HAZARDOUS OCCUPATIONS

(Use This List to find Diagnostic Signs in Occupations)

The capital letters after each occupation, A, B, C or D, refer to the particular hazard, whether Dust, Heat, Humidity or Poisons. The Arabic numerals following the capital D signify the particular poisons to which the workers in the occupation are exposed.

EXAMPLE:—Stiffeners (felt hatting), D 15.

Such workers are exposed to the fumes of wood alcohol which cause, among other symptoms, the following, which can be observed by you: Inflammation of the throat, mucous membranes and of the air passages, conjunctivitis, affection of the retina and optic nerve, dermatitis.

EXAMPLE:—Patent leather workers, B, D 13, 24, 9, 2, 15.

Such workers are exposed to heat as well as to such poisons as lead, turpentine, carbon monoxide, amyl acetate and wood alcohol.

Acetylene gas makers, D1, 21, 18.	Batch makers (glassworks), A, D 13, 5.
Acid dippers, D16, 22, 12.	Batch makers (rubber works), A, D 13, 4.
Acid dippers (electroplating), C, D12, 16, 22.	Baters (tannery), C.
Acid finishers (glass), D 12, 22.	Beamers (textile), A.
Acid makers (chemicals), D 12, 16, 20, 22.	Beam men (tannery), C.
Acid mixers, D 16, 22.	Beamsters (tannery), C.
Acid recoverers (chemicals), D 16, 22.	Beatermen (paper and pulp), C.
Acid weighers (chemicals), D 12 or 16 or 22.	Beater tenders (paper and pulp), C.
Aeroplane factory workers, D 10.	Bed rubbers (marble and stone), A.
Aeroplane-wing varnishers, D 10.	Beer vat varnishers, D 15, 13, 6, 24.
Ammonia salts makers, B, D 1, 21, 20.	Bench molders (foundry), A.
Alcohol stiffeners (felt hatting), D 15.	Benzol still workers, D 6.
Aldehyde pumpmen (chemicals), D 15.	Bessemer converter workers (iron and steel), B.
Alkali workers, D 11, 12, B.	Beta still operators (paint), B, D 22.
Annealers, B.	Bevellers, A.
Art glass workers, D 13, 24, 2, 15.	Billet mill workers (iron and steel), B.
Artificial flower dyers and finishers, D 15.	Blacksmiths, B.
Artificial manure makers, A, D 18, 22, 12, 20, 21, 16.	Blast furnace workers, B, D 20.
Asbestos workers, A.	Bleachery workers, D 11, 20.
Babbit makers, D 13.	Bleachery dryers, B, C.
Bakers, B.	Blockers (felt hatting), C, D 9.
Bar mill workers (iron and steel), B.	Blooders (glove leather tanning), D 4
Basic slag (artificial manure) workers, A.	13.
	Blooming mill workers (iron and steel), B.
	Blowers (felt hatting), A.

*Read before the Fifth Annual Meeting of the American Association of Industrial Physicians and Surgeons, in joint session with the Health Service Section of the National Safety Council, Milwaukee, Wis., September 29, 1920.

†Philip Leiboff born June 16, 1892, died September 23, 1920. In his untimely death, the field of industrial hygiene lost a most promising contributor. The work described in this paper was largely his creation. For years, he had gathered together material on the effect of the industrial hazards upon health. He had planned to extend his observations along many allied lines and his files remain full of projects and of researches only partially completed. This work, for which his equipment was excellent, must now fall to other hands. Those of us with whom the few years of his creative life were passed will long remember him and favorably. L. I. D.

1. Copies of the pamphlet "Occupation Hazards and Diagnostic Signs" may be obtained by writing to the Statistical Bureau, Metropolitan Life Insurance Company, 1 Madison Avenue, New York City.

Very serious limitations of the pamphlet are clearly realized. It is very far from complete either in the list of hazardous occupations or in the list of hazardous conditions or substances met with in industry. The list includes only about five hundred occupations and only the most prominent of the health hazards. Furthermore, as the pamphlet was intended primarily for the use of the medical examiners of the Metropolitan Life Insurance Company, it embraced only those matters which would be important in their special work. A number of important considerations which would have been included in a more general work were omitted. Such occupational diseases and conditions as anthrax, caisson disease, and electric shock were omitted because they would not occur in the course of medical examinations for life insurance; so also were industrial hazards which have only local or temporary effects, poisons not frequently met with in industry, and, also, such which cause disease, whose symptoms are subjective and require a clear description by the per-

son examined. In short, the work was limited to an effort to acquaint an insurance medical examiner with the recognizable symptoms of the chronic effects upon health of the more important occupational hazards, excepting the most obvious ones.

The possibilities of and, in fact, the need for the extension of this work is very clear. The realization of such extension must be left to such associations as the Health Service Section of the National Safety Council and the American Association of Industrial Physicians and Surgeons. We recommend that a committee be appointed from these two groups to consider ways and means for extending the work we have begun. Such a committee could get in touch with industrial physicians and factory inspectors, send them copies of our pamphlet and obtain from each answers to questions similar to the following:

1. What additional hazards do you note for any of the occupations listed?
2. What particular occupations involving hazards are you familiar with which are not listed in the pamphlet sent you; what are the conditions of work and hazards involved?
3. What symptoms do you note for industrial hazards which differ from those tabulated or which are in addition to them?

The results of such an undertaking, if carried out earnestly for a period of years, should be very valuable indeed. A reference work of the highest order both in completeness and in scientific accuracy would be produced, industrial hygiene would be most stimulated as a branch of preventive medicine, and much valuable health work accomplished. Thousands of persons suffering from occupational disease would ultimately be discovered and the first step taken to control the conditions which make for such disease.

INDUSTRIAL PHYSICIAN DIES

Dr. H. H. Smith, chief surgeon of the American Rolling Mill Company, Middletown, O., passed away in Indianapolis, Ind., November 22, 1920.

Dr. Smith was one of the outstanding figures in industrial medicine in the United States. He did not take up the study of medicine until he was thirty years of age, having spent his earlier manhood in teaching school and other work along educational lines. It was his conviction that in preventive medicine lay the great hope of the world, and he saw that the place to work out his theory was within institutions where large numbers of people could be dealt with as a unit.

Dr. Smith was born in Kokomo, Ind., on June 6, 1872. He graduated in medicine from Indiana University in 1907. After serving as an intern in the Deaconess Hospital at Indianapolis, Ind., his first position as a physician was in the State Reformatory at Jeffersonville, Ind. Here he had his first opportunity to develop plans for institutional work along medical lines. In 1911 Dr. Smith superintended the plans for a new hospital for the American Rolling Mill Company of Middletown, O., and became its physician. For the first five years he was the only physician in charge. Later the medical organization grew until at the time of his death it numbered three physicians and thirteen nurses.

Dr. Smith's warm personality helped him to win the hearts and confidence of those he served. He early realized that the success of industrial medicine is largely a matter of building up confidence between the organization and the medical department.

Figure 2.

Hazards and Diagnostic Signs

HEALTH HAZARDS	SYMPTOM, CONDITION OR DISEASE TO LOOK FOR	INDUSTRIES, PROCESSES AND OCCUPATIONS WHICH OFFER SUCH EXPOSURE
A. DUST		
Mechanically or chemically irritating, or infectious dust.	Chronic catarrh of the respiratory and digestive tracts; inflammatory condition of the eye, ear, nose and throat; ulceration of the nasal passage; fibrosis; tuberculosis.	Marble and stone, mining, phosphate, cyanamid, asbestos, textile, alkali, button, etc., industries; grinding, sand blasting, polishing, cutting, clipping, buffing, mixing materials in rubber, glass, pottery and chemical industries; sorting of rags, file making, comb making, etc.
B. HEAT		
Including cold and variations in temperature.	Anemia, general debility, catarrh, "colds," rheumatism, stiff joints, lumbago, Bright's disease, skin eruptions, cancer, fibrosis, premature old age, cataracts, retinitis, conjunctivitis.	Iron and steel mills, smelters, foundries, metal-working plants, glass factories, electro-chemical works, laundering, glue manufacturing, sugar refining, bakeries, confection making, ice manufacturing, kilns in potteries, color works, etc.; tempering and annealing, canning and preserving (hot steam process); dining car workers, cooks, stokers, firemen, stillmen, blacksmiths, furnace tenders.
C. HUMIDITY		
Including moisture, wet, dampness, etc.	Diseases of the respiratory passages, neuralgic and rheumatic affections.	Pulp and paper mills, tanneries, felt hatting (wet processes), textile industries (especially cotton), furniture (glue department), sugar refining (filtering process), canneries, oilcloth and linoleum (drying rooms); gluing, clay working, plaster of Paris working, steam vulcanizing, paint manufacturing (color department), dyeing and cleaning.
D. POISONS*		
1. Ammonia.	Irritation of the mucous membrane and chronic bronchial catarrh, edema of the lungs.	Coke ovens, gas plants, ammonia gas collection and ammonium compounds making, ice manufacture, refrigerator plants, mirror silvering.
2. Amyl Acetate.	Nervous symptoms and palpitation of the heart.	Lacquering, enameling, bronzing, gilding, leather outfitting, patent leather making, wiring for incandescent lamps and oilcloth manufacturing; polishers and buffers.
3. Aniline Oil.	Profound anemia, slowing of the pulse, disordered nervous symptoms, cyanosis, spasmodic muscular pains.	Manufacture of aniline oil, paints, colors, dyestuffs, explosives, photographic materials; rubber compounding and mixing, lithographing, printing, dyeing.

*For the data presented under this heading, the revised and translated "List of Industrial Poisons" compiled by Sommerfeld and Fischer, has been drawn upon largely. The arrangement is similar. (See U. S. Bureau of Labor, Bulletin No. 100, May, 1912.)

PRACTICAL METHODS OF REDUCING FATIGUE*

By FRANK B. GILBRETH, LL.D., MEM. S.I.E., MEM. A.S.M.E., AND L. M. GILBRETH, PH.D., MONTCLAIR, N. J.

AT THE present stage in the progress of fatigue elimination, not much will be gained by disputes as to the relative efficiency of various methods and devices.

The important thing is to eliminate *at once* all unnecessary fatigue that can be located, and to insure that the worker is not fatigued by his day's work beyond the point where he can recuperate completely during a night's rest.

Those interested in the subject are acquainted with the necessity of making a fatigue survey to determine what is being done along these lines and what can profitably be done; with the benefits of a "museum" where fatigue eliminating devices from all sources may be collected through photographs, drawings, and, preferably, models; with the necessity of arranging all possible work so that it can be done part of the time standing and part of the time sitting; with the importance of supplying work chairs and rest chairs, fitting the special demands of the work, and the needs for recuperation from it; and with the importance of rest periods.

Test Value of Rest Periods

Too much time has been spent lately in dispute over the necessity for and duration of rest periods. The scientific determination of the need for and the length of such periods is no work for an amateur. The best practice demands that such periods be introduced wherever there is a question as to the fatigue of the worker, with an understanding that the arrangement is temporary. Further investigations may show that the work provides sufficient rest periods because of unavoidable delays, or that a change in methods may make different rest periods desirable. No one has a right to discredit or discard rest periods after a half-hearted attempt to install them. Usually, when changes are made, so many factors are involved that it is almost impossible to place the blame for a failure where it belongs, and too often it is attributed to the rest period, which has probably been introduced in spite of the opposition of some, who are only too glad to accent anything that may seem to discredit it.

The use of the Home Reading Box, the benefit of change in posture, the influence of lighting, heating, and other work conditions are well understood. These are all very practical aspects of the work. Equally practical, though perhaps not so well understood, is the new attitude toward work that is a part of fatigue elimination. Viewed from the fatigue study standpoint,—which is closely related to the motion study standpoint,—all work becomes interesting,—becomes a worth while subject to investigate. Unless already investigated and standardized through motion study, the work method under inspection is probably wrong and offers a field for improvement. The problem may be considered in various ways: for example, as one of (1) worker; (2) surrounding conditions and tools; (3) motions. Again, as a problem of decisions and motions, each part of it may be considered as consisting of three types of motions: (1) those almost beyond the capability of the one performing the work, but which may be learned by him, and which require the best in him; (2) those well within the grasp of the person doing the work, which he may easily reduce to habit and perform with ease and pleasure; (3) those extremely simple for the

one doing the work, which may well be passed over to someone of less experience, training, or capability. Again, the work may be considered as consisting of cycles of motions, the motion cycle having sixteen elements in different combinations. These elements are: search, find, select, grasp, position, assemble, use, disassemble or take apart, inspect, transport, load, pre-position for next operation, release load, transport empty, unavoidable delay, avoidable delay, and rest for overcoming fatigue. Again, the work consists of the motions, and the resulting fatigue—the problem being to accomplish the work with those motions which are produced with least fatigue.

Devise the One Best Way

Some of the investigations suggested by these methods of attack upon the problem require intensive training and special apparatus. Many, however, may be made without special training and with no apparatus, through keen observation and interest in the subject. The fundamental idea is to *think* in elements of motions and the resulting fatigue, with the aim of devising the one best way to do the work. In order that this may be most profitable, a laboratory, or at least a laboratory trained worker, to measure and coordinate the findings of the thinkers, will mean the greatest economy of effort and most profitable and permanent results. Such laboratories and such workers are becoming more and more a part of industry. The supply will meet the demand, and will be forthcoming quickest when everyone interested in fatigue goes through the preliminary stages of waste elimination for his own work processes, in the plant and out.

Investigations in the science of fatigue elimination are going on everywhere. The Society of Industrial Engineers has established an International Committee for the investigation of problems of eliminating unnecessary fatigue in the industries. This Committee is collecting data on fatigue elimination in all countries and is glad to cooperate with all interested in the subject, to receive into its membership a representative of any body interested in the subject, and to place its findings at the disposal of everyone. Data is being collected in the fields of psychology, physiology, psychiatry, and the allied sciences. Thinkers in all countries are attacking the problem. We are bound to have the facts placed at our disposal. The important thing is to introduce broadcast the *practice* of studying actively with the aim of eliminating fatigue and of supplying fatigue eliminating methods and devices at the earliest possible moment.

If every member of the community would study his own activities for *one day*, and try to carry out the improvements that are bound to suggest themselves, no matter in what amateur fashion, the solution of the problem of eliminating unnecessary fatigue would be assured. The remedy lies simply in the direction of the attention toward the special problems at hand. Intelligent study of these problems insures a method of correction adapted to existing conditions. As for the cost involved, much important work in this direction can be accomplished simply by learning to *think* in terms of cutting out fatigue, but even when elaborate methods are necessary and costly methods of investigation are employed, fatigue elimination campaigns more than pay for themselves in results both in increased efficiency and in cooperative effort.

FUNDAMENTAL REQUIREMENTS FOR SUCCESSFUL MEDICAL WORK IN INDUSTRY*

BY W. A. SAWYER, M.D., MEDICAL DIRECTOR, EASTMAN KODAK COMPANY, ROCHESTER, N. Y.

IT IS my desire to focus our attention on what seem to be the logical basic essentials for industrial medical practice. There are individual ideals, held by at least some of us, which keep us ever pushing on toward a fuller program, which is all very well, if at the same time the snare of too much differentiation is avoided and all possible progress is made along lines of cooperation and interest from the upper executive realms down through the medical staff to the rank and file. Therefore, first of all there needs to be a spirit of sympathetic understanding from the executive head of the concern; in the second place, it is impossible to emphasize the value and need of adequate personnel—adequate, first in quality, and then quantity. A service is hopelessly handicapped without the spirit of sincerity and confidence, emanating from the head of the medical organization, reflected and augmented by the personality of each assistant, doctor, nurse, and even the stenographer, and this must be regarded as essential in order to warrant the faith and assure the support of the employer and the employee.

Plan According to Needs

It seems hardly necessary to mention equipment and quarters, for while they are of no small importance, there can be no definite rule universally applicable. Granted my first condition, viz.,—cooperation from the top—and these will adjust according to the need. That the quarters should be clean, cheerful, and businesslike goes without saying. It should accommodate with the necessary privacy and equipment. This should include an adequate system of records as well as the medical and surgical accessories which the work may demand. Elaboration of armamentarium, however, is no indication of the success of the Department, but the kind of a program, the development of the possibilities within the scope of the service constitute the best evidence of the usefulness of the organization. I once visited a factory dispensary where a full time doctor was in charge and where it was only necessary for an employee to come to the doorway and ask for this or that medicine, much of which was in liquid form in bottles all labeled with directions, which was handed out without a question or a thought as to why it was wanted or how it was to be used. A large percentage of the clientele of this physician never crossed the doorsill and frequently took with them this or that favorite remedy for the use of a fellow worker. This might be called industrious medication but not industrial medicine. The industrial physician who realizes that certain changes are unavoidably overtaking the field of medicine and who contributes toward giving hygiene and education the place they are inevitably to assume is surely adding length to his stride for success.

Time does not permit of a comprehensive survey of all that enters into success in this field, for there is as much needed here as is needed elsewhere in the field of medicine, but a consideration of its manifold opportunities always brings out one important fundamental, namely, the honest, salutary, and intelligent physical examination.

The first thing that enters the mind of a doubter of the value of the routine physical examination is the supposedly unwilling or even antagonistic attitude on the part of the employee. In assuming that this attitude is characteristic it is my experience that too much is taken for granted, and difficulties arise because not enough thought is given to the method of procedure. Thorough periodical physical examination, properly recorded, carefully explained to the examinee, with the necessary provision for following up the delinquents and defectives, develops a very solid basis for a thorough preventive and curative program. This service, being part of a general program, can be understood, then appreciated, and ultimately greatly desired by the recipient. It may even be expected that in some not far distant day the value of this procedure will be such that these examinations will be asked for by the applicants for employment, in order that they may be assured of greater safety and efficiency through proper placement, knowing that such procedure will add greatly to their welfare. The attitude of the industrial physician can do much to shape this end.

When physical examinations are mentioned, all that is usually thought of is a rather superficial survey at the time of employment is sought with an organization. Anything beyond this is neither contemplated nor hoped for. Such a cursory examination may be better than none; but where can the line honestly be drawn? The *raison d'être* for any medical department, the one mutually advantageous to both the employer and the employee for its maintenance, is to sustain good health for each individual, with the placement of every worker at the job for which his physical qualifications at least do not unfit him. This not only requires a thorough examination but obviously pre-sages job analysis, for how can the doctor determine a man's fitness to do a certain task unless he knows just what that job entails? In many plants neither the doctor nor employment department knows the requirement of a given job. By no means have we begun to realize all the possibilities of the proper selection of workers from the physical standpoint, and we haven't even scratched its surface in regard to the mental adaptations of the worker. It doesn't require much familiarity with the processes of mental analysis to become impressed with its pertinence to this subject, and there seems no reason why this may not become, eventually, a very important phase of the complete physical examination, this to include not only intelligence tests, but something which will bring out motives, desires, inherent stability, and balance. Let this engage your thought as you go about your work, and see if something of benefit may not evolve.

Estimate the Human Machine

But to return to present requirements. When the physical examination is a means to a worth while end, and is not made an end in itself, little opposition arises. As preventive measures are extended, less of the narrow viewpoint will be in evidence. Then, too, much of the old time opposition to the physical examination, as too often simply meant rejection, will pass away as we come to feel that every man has a right to work, and that jobs must be found in which all can work with safety.

*Read before a joint meeting of the American Association of Industrial Physicians and Surgeons with the Health Service Section of the National Safety Council, September 29, 1920, Milwaukee, Wis.

It may be in order to detail here my conception of conducting the thorough physical examination which is a satisfaction to all concerned. Assuming that the applicant has been interviewed, perhaps shown the job, trade tested, and subjected to intelligence tests, and is at last sent to the doctor for a physical examination. With him, as a matter of routine, come the specifications of the job for which he is scheduled. First the preliminary data are obtained by a nurse or a clerk, together with weight-taking and eye and ear testing. An introduction to the doctor then takes place, when ensues a rather detailed questioning as to previous medical history. This is done to advantage by the doctor, as it gives him an opportunity to size up the individual. Then comes the actual physical examination, which should be as painstaking as that of the best insurance companies, if not as that of our army. Only on such an examination can a true and complete estimate be made of the human machine. If an impairment is found, it should be explained briefly, though sympathetically; if cause for rejection is found, such information should be given to the examinee as the case indicates. Perhaps this might be supplemented by little leaflets prepared for such exigencies, to explain in a more detailed way just what the condition involves. If the man has not previously been aware of the condition, he will leave feeling perfectly certain that real service has been rendered; whereas, if the examination is made in silence and the report of rejection returned to the employment department in a sealed envelope, it may be counted upon to result in resentment or ill feeling. Only by putting all the cards on the table is greatest satisfaction rendered. At the conclusion of the examination the doctor should hand the examinee a blank form on which is asked questions relating to hygiene and habits and the general family health. In doing this it should be explained by the doctor that a written report of the examination will be available to the examinee by properly filling in this blank and returning it. As a rule, more reliable answers to such questions are obtained when there is time for some consideration. When this information concerning personal habits and family health is received, it should be reviewed in conjunction with the physical examination and the report sent out outlining any impairment or correction of habit which seem indicated. A statement should go with it saying that this report is a basis for future examinations to which the employee is entitled yearly or oftener, if necessary, explaining that the maintenance of health is an asset, and any real advancement or promotion in business is precarious without it; and that health is more often than not the result of vigilance and proper living. The future relationship of the medical department to this individual is built upon this initial contact and understanding, for better or for worse, as the case may be.

If the employee is fit physically, then the function of the medical department toward him is preventive, through health education; if, however, he is in need of better glasses or dental attention, or has an impaired heart, then "Follow-up" is plainly the duty of the department, and curative as well as preventive measures are in order. Here we are immediately concerned with good working conditions, sanitation, proper nutrition, studies in fatigue, etc. Only by thus intelligently, and I may add, scientifically, beginning a relationship with each new employee can the medical department adequately cope with the problems as they arise, in this way largely will the employee be impressed with the ability of the medical department to serve his needs.

The plan herein outlined would need modification or

adaptation to each industry. Groups of aliens, for instance, who understand but little English, increase the difficulty, and it might be that service in conjunction with a sick benefit association, having periodic physical examinations as a requirement for membership, would afford the requisite point of contact. Some opening can usually be found. If the intelligence of the worker does not permit him to take advantage of what is offered, the medical department has recourse to a persistent program of education and follow-up, not failing to avail itself of the advantages of publicity work, urging and arousing the man with impaired physique to remedy the condition. Eventually the few who refuse altogether to heed advice may be discharged. The extent to which this can be done, together with the percentage of rejections at the time of initial examination, bears a direct proportion to the labor supply. If industry is to make the most of its findings, it should be able to pass these impaired workers in each industrial community on to organizations which find satisfactory employment for the crippled and for those with weak hearts or lungs. These men and women who are not able to pass as able bodied workers should have the opportunity for appropriate training and subsequent positions just as rightfully as those incapacitated from accident. Inasmuch as the goal of industrial medicine is more efficient and happier workers, it should be our constant aim to pass at the time of initial examination only those individuals who are able bodied and properly equipped to be able to stand the strain of our present industrial life. Those who are passed certainly deserve the opportunity of care and supervision, in order to maintain their potential qualities of strength, or to eliminate in due time an impending handicap.

The Records Have Value

The value of periodic re-examination depends very largely in the efficiency and the use made of the records kept. Industry generally is not making the most of its advantages here. Organizations long established frequently find that among their older employees, looked upon as healthy, are those succumbing to ailments of various kinds and often sudden death results from conditions which have been developing gradually, diseases which they might reasonably have expected to prevent or at least retard by a systematic periodic survey or inventory of the human physical equipment. The value of such survey is by no means confined to the employee but would often save years of valuable experience to the company. This is but another evidence of what almost seems a national trait—failure to conserve. We waste our natural resources, many fail to conserve their finances, and most of humanity are prodigal with their health, even though all the while we are brought closer to the realization that taking care of what we have pays every time. As applied to the unskilled employee, it is, perhaps, from the company's position not so *obviously* worth while; but when the turnover can be held within normal limits it will surely bring results. Of those who handle food in any way—such as in company restaurants—examinations every three months should be made, together with exacting supervision on the part of the one in charge, to see that a very high standard be maintained in regard to colds or other contagious conditions.

With respect to periodical physical examinations for all executives, nothing in industrial medicine can pay such handsome dividends and so completely sell the worth of the work as a whole. It is a notable fact that most men holding large positions, because of their responsi-

bility, infringe on their health and fail to take into account those things which make for continued efficiency and longevity. Each year records a large number of men in high positions dying prematurely of diseases that could have been prevented. Now, I realize full well that merely examining such men yearly or half-yearly and appraising them and giving advice does not necessarily spell conservation, because most of them are in a position to receive good advice. Only when there is a well established channel for taking care of such cases will results be obtained. When the medical department comes into the possession of facts which plainly indicate that a given executive needs rest or treatment, the word should be passed on to the head of the company or of the department, when the necessary pressure could be exerted to bring about proper action, and thus many years of useful service by so-called invaluable men could be saved to the company.

A careful study of absenteeism from sickness reveals many interesting facts. This is best made at the time of stated physical re-examinations when records of absenteeism have been consulted in connection with what is learned from questioning. It may be found by such examination that the employee is no longer fitted for the work he is performing and perhaps a transfer or short rest will re-establish health.

Carry the Obvious Risk

Industry cannot afford to carry too large a percentage of individual liabilities or potential hazards; yet, as it is agreed that everyone should be given the opportunity to work at some form of profitable employment, a certain proportion of these handicapped cases must be absorbed. The workmen's compensation boards need to cooperate if industry is to admit to its ranks men and women who are obviously accident liabilities. At present no protection is given to the employer and, naturally, he does not wish to take on the obvious risk.

Whether we like to admit it or not, most of us realize that the type of medical care which the average person receives is not always the best; time and equipment on the part of the average practitioner are often lacking, if not ability and desire. How often do you hear of this or that worker who has been to not only one doctor, but several, without receiving an adequate "going over"? One man treats him for this and the next man treats him for that, and at the end of the period the individual knows no more about his condition than at the start and he may be far from being any better. Quite recently a girl stepped into one of our dispensaries and said she would like to know whether we thought she had appendicitis. She was questioned and examined carefully and told that the indications were very slight and given some advice. She then related that her doctor told her she might have to have an operation and she didn't care for it. She was asked to what extent her doctor had examined her and she said he felt of her side as she stood by his desk, making pressure over the region of the appendix through her clothing. She flinched somewhat and he then gave her some tablets and told her that if she were not better in a few days, it would be necessary to have the appendix out. That actually happened and is, I fear, but an example of the sort of thing that is occurring daily. Any doctor engaged in industrial work can repeat many such instances, all of which lead to the conclusion that the greatest need today for the worker in our industries, as well as for all our population, is a chance to know the truth. This is not offered as a criticism, but it is a fact to be reckoned with.

Is it not a logical development for the periodic physical examination to become a diagnostic clinic? In this, our opportunity to give the worker the truth as best we see it, thus forewarning and forearming him, is perhaps the most effective weapon we have against charlatans, quacks, and pretenders generally. For instance, are tuberculosis associations and clinics ever going to gain real headway against the disease until industrial communities and the business world generally make a thorough search for it, both at time of employment and later? And in attempting to uncover these many hidden cases, let us not forget that facilities for their treatment and care are shamefully inadequate and few. Cannot industries group together and eventually find a way to conduct their own sanatoriums at a minimum cost, or with a united front demand that public health departments bestir themselves to provide accommodations suitable to the need, and free from the hampering influence of civic politics? A system of physical examinations for workers which gives a diagnosis and points the way to continuous health is joining hands with the new vision of public health which now seems to be finding expression throughout the country, in legislation and propaganda for the mother, the baby, the child, the young boy and girl, and, finally, for all adults. Once the importance of health as a business asset or a basis for advancement in life is sufficiently understood, the helps offered will be popular and real results will follow. The movement toward health conservation is expressing itself through various channels. The general public is providing for it, accepting and demanding it as its right as it becomes health conscious.

The part that industrial medicine can play in this large program is very vital. Many things in the way of public health program can be inaugurated and carried out with the cooperation of industrial medicine, but first and foremost must be considered carefully the fundamentals of successful industrial work; for until in each unit right plans and methods are worked out, the greater achievement will still elude our grasp.

Summary of Requirements

Successful medical work in industry, then, must have:

(1) Sympathetic cooperation from the top of the organization; (2) a personnel providing a staff of adequate proportions and character; (3) equipment adapted to the requirements of the department; and (4) a program in which ideals plus daily practice will result in consistent growth.

A physical examination, complete and painstaking, is of major importance.

(1) Initial or entrance examinations are for purposes of placement and exclusion. To acquaint worker with his physical impairments. This can be made interesting and helpful to the worker. Get his interest; his cooperation in the end makes for the more efficient and contented worker, which is our goal.

(2) Periodic re-examinations not only of the rank and file, including special groups such as food handlers, etc., but also the executives of the organization. Follow-up to see that work does not prove hazardous and that advice as to corrections is being followed.

(3) It contributes toward reducing sickness incidence—hence cuts down absenteeism.

(4) Promotes longevity of service.

(5) Dovetails with efforts of public health work in detecting contagious disease and should be the surest and most effectual way of finding those members of a community suffering from tuberculosis or other prevalent

diseases. Greatest opportunity today of medical science is through prevention; and physical examination is fundamental in prevention.

(6) Physical examination leads into all other branches and parts of medical work in industry; diet, recreation, mental hygiene, housing and working conditions, fatigue, and even to the training and raising of children, and the health of the worker's entire family.

(7) Finally, physical examination will often provide a diagnosis and help effectively to fight quacks, charlatans, and other pretenders. It will teach the worker the truth, something he is mightily interested in, thus he will be forewarned and prepared. Systematic care, with periodic physical examination saves the workman on the one hand from ill advised treatment, and on the other from the neglect of important conditions.

OREGON SYSTEM OF MEDICAL SERVICE*

BY F. H. THOMPSON, M.D., MEDICAL ADVISER, OREGON STATE INDUSTRIAL ACCIDENT COMMISSION, SALEM, ORE.

THE Oregon system of medical service is similar to that of some other states, but Oregon is probably the first state to put into active operation a regularly equipped physiotherapy department. The Oregon law, aside from administering a compensation fund, makes provision for the prevention of accidents, this work being done in conjunction with the State Labor Commission; but in case of accidental injury, covered by the act, the medical department aims to care for the injured as completely as possible. This care will be divided, for the sake of convenience of consideration, into four general sections: (1) primary care; (2) proper after-care; (3) reconstructive surgery; (4) physiotherapy.

Practically, the injured has the right of selection of his own physician. This does not apply in hospital contract cases where the contractor furnishes medical aid through a contract physician. In Oregon the state law admits of such contractors, under certain stipulations. However, in case where the contract physician has proved to be incompetent by bungling of cases, the Commission reserves the right to demand his removal and his replacement by a competent physician; if refusal is given, the contract may be canceled. Or, in case the Commission considers that the man is not receiving proper care, it reserves the right to select a physician other than a contract physician for the completion of the care of the case; that is, to transfer the man to a different physician, or give him a list of three or four physicians, capable and well qualified for that particular type of case, and allow the man to select from the list the one whom he desires to render the treatment. All medical care, even by these selected surgeons, is done according to an adopted fee schedule. The schedules for the states of Oregon and Washington are identical and accepted as standard for industrial surgery by the state medical societies of the two states, respectively. The fee schedule is such as to reasonably remunerate for competent care, and very little complaint is ever raised—and none of serious import. If a case does not progress satisfactorily it is reviewed by the Commission, or a consultation ordered, and any special care needed is provided. This is done in hospital contract cases, also, at the expense of the person holding the contract. Radiographic service is paid for according to schedule, but excessive and unnecessary duplication of plates is not tolerated. The Oregon law provides for transportation and hospital and surgical care and nursing. While ordinarily \$250 is supposed to be sufficient to cover the expense incurred in any ordinary case, there is, in reality, no limit to what may be expended for the restoration of a workman, provided that prior to expending more than \$100 for hospital, \$100 for surgical, and \$50 for trans-

portation and other expense, the Commission be consulted and its approval for a greater expenditure obtained. This provision prevents an unscrupulous surgeon from piling up an enormous bill without knowledge by the Commission. This excellent provision makes possible two very important features of the Oregon system, namely: Reconstructive surgery and physiotherapy.

Surgery for Restoration

There are many cases calling for reconstructive surgery. This is especially true in maltreated fractures and soft tissue injuries that can have restoration of function by competent and well timed surgery. Many cases have been so treated under the Oregon Commission with most gratifying results. Examples are: a Pott's fracture that has been unreduced and united in vicious position, thus destroying the proper relationship between the ankle mortise and astragalus and throwing off center the weight bearing line through the astragalus, or the similar disalignment of weight bearing in unreduced fracture at lower third of tibia and fibula, or in a fracture in which rotation of the fragment has occurred, and in ununited fractures; also tendon contractures and peritendonous adhesions and severed tendons that have not been sutured, or unsuccessfully so, and many allied conditions. The Commission in these cases selects the surgeon for the particular work in hand and orders the injured man to report to him for such care or operation as deemed best. Generally the man is anxious for restoration, but there are exceptions. In the cases that are not prone to accept restorative surgery, the disability award is made on the basis of disability that one would reasonably suppose to exist had the injured submitted to operation, and not on the basis of disability existing without operation, the one object, of course, of reconstructive surgery being to restore the injured to as nearly a normal condition as possible and thus aid him in the strife for existence. No permanent partial disability is awarded until all possible restoration of function has been accomplished. This makes essential the practice of physical therapeutics.

The past experience in Oregon produced so many cases of fractures too long splinted, in which peri-articular fibrosis had occurred, atrophy of muscles and muscle contracture, leaving ankylosed or partially ankylosed joints, that it was believed expedient to try out massage, physical manipulation, and electricity and hydrotherapeutics to see what results might be obtained toward restoration of function. Accordingly, a great many cases with marked disabilities were given such care, resulting in such marked and early improvement that it was deemed advisable to make a study of the work being done in Army reconstruction camps. This study was carried on by the author and Commissioner Marshall, who, after seeing the work that was being accomplished by proper and sometimes pro-

*Read before the Seventh Annual Meeting of the International Association of Industrial Accident Boards and Commissions, San Francisco, Calif., September 20-24, 1920.

longed after-care, decided to recommend to the Oregon Commission the establishment of two fully equipped physiotherapy departments; one to handle cases coming from the Columbia River Basin and the eastern part of the state, and one for the Willamette Valley and the southern part of the state. This work was considered so important that the departments were fully equipped with hydrotherapeutic, electric, and other equipment and trained Army aids employed to carry on the work; each department being under the direct supervision of returned overseas service men who had had splendid orthopedic training and were familiar with the various angles of physiotherapy. With such organization all serious fracture cases as soon as union has occurred, are ordered to one or the other department for early treatment, with the object in view of lessening permanent disabilities and shortening temporary time loss. Many permanent partial disability cases are such because too much time is allowed to elapse before passive and active use. Contractions and fibrosis of too long standing can not be completely overcome. The results have been most gratifying. The surgeons throughout the state, with few exceptions, are glad to have the after-care off their hands for, primarily, their offices are not properly equipped for such treatment. And again, the average surgeon is not fully posted in the methods of proper physical treatment in the after-care of fractures and other like conditions for, as a rule, their main object is to secure a union in good alignment, leaving nature and ordinary use to accomplish what they will in the restoration of function. There was some objection on the part of some surgeons who imagined that the calling of the patient for such treatment was a discredit to their work. This objection, however, was overcome when the object of the treatment was explained. Now, when a patient is called in for such treatment the physician is sent a carbon copy of the order stating the reason for calling the patient in. Again, this early review by the medical department makes possible the detection of remedial deformities at a sufficiently early state for correction. In every such case, or in case the patient is transferred from one physician to another for special care, the original physician, in case of fracture or other specific condition, is paid in full for the care of the case, as per the Commission's fee schedule, and the special treatment is paid for in addition. Of course, as far as physiotherapy is concerned, this work is done by salaried aids. The hospitals do not object to the establishment and conduct of these institutions, for they are essentially institutions for follow-up or after-treatment and involve ambulatory cases only, and, under the Oregon law, when a case becomes ambulatory, it is no longer a fit hospital case, and if the man remains at the hospital it is at his own expense, as the object of compensation is to pay sustenance during the period of incapacity. In Oregon the hospitals care for the Commission cases under a set fee schedule.

To give some idea of the magnitude of the work will say that at present there is an average of 605 treatments per month given at the Portland department and an average of 534 at the Salem department.

The Portland department is under the direct supervision of Dr. Richard B. Dillehunt, dean of the University of Oregon Medical School and a returned major in overseas service. The Salem department is under the direct charge of Dr. C. A. Downs, a captain in the orthopedic overseas department, and these men determine what treatment shall be had, supervise the giving of such treatment, and determine when treatment should be terminated. Permanent partial disabilities are estimated by the chief medical examiner.

Study Humane Side of Problem

When physiotherapy has accomplished its work, the Oregon system goes a step further and gives its unfortunates who have suffered major disabilities of a permanent nature vocational retraining. This work is done only after the permanent partial disability award has been made. The first law of nature is self-preservation. The able bodied and strong mentally and physically can well fulfill the law of the survival of the fittest, but the less fortunate deny the proposed law that all men are free and equal and prove that the greater the handicap the less possibility of successful strife in the commercial world. This holds true in the world of industry. This intensely economic, social, and humanitarian study and problem is, of necessity, boldly faced by the state industrial accident commission, and it was deemed a wise provision to make it possible that the ones who were greatly handicapped might be placed on a little more equal footing with the unhandicapped by being retrained to some line of work that they could adequately fulfill. It is the belief of the Oregon Commission that the compensation law is a law not for the employer only, and not to solve a sociological problem only, but, primarily, is a provision to aid the man who has offered his fingers and hands as a sacrifice on the altar of industry, and to make it possible for those dependent upon him to meet at least the bare necessities of life during the period of the incapacity of the bread-winner, and, if it be possible, surgically or educationally to restore the injured to usefulness in some plane of active life. They, therefore, have succeeded in securing the passage of amendments to the Oregon act that virtually remove the limit of what they may do for an injured workman if by so doing it will restore him to proper earning capacity and remove the possibility of himself and his family becoming dependent upon the alms of the public.

Briefly summarized then, under the Oregon law the injured man has the free choice of his own physician, with the reservation that the Commission may select a physician to make a special examination or give special treatment if the case may justify it, thus reserving to the medical department, ultimately, full control over selection of physicians.

Reconstructive surgery is the rule, if properly indicated, and to my mind is one of the greatest steps the Commission has taken. This, I believe, and know, from actual observation of what can be accomplished from such measures.

The Oregon system certainly urges physiotherapy as the only proper procedure to shorten time loss and lessen permanent partial disabilities. When all possible has been done for restoration of function we advocate strongly vocational retraining for the injured workman who has suffered a major permanent disability. All work is done according to fee schedule and all hospitals are paid according to fee schedule. Ambulatory cases are considered non-hospital cases.

In cases of amputation temporary total disability is continued until an artificial limb can be secured and the State commission pays for the artificial limb.

The State Industrial Accident Commission of Oregon believe it is its duty to disseminate the principles of accident prevention and to do all possible toward restoration of the severely injured to some phase of industrial usefulness. It is their hope and desire that the administration of the medical department be so conducted as to be the most helpful to the industrially injured, most economic to society, and satisfactory to the employer.

THE HUMAN FACTOR IN INDUSTRY

THE development of modern industrial history has been a war against waste, seeking economy of effort in methods of production and the utilization of raw materials. Workers and capital have been gradually concentrated under one management; the machinery of manufacturing carefully watched and developed to such an extent that the human factor was until recently practically ignored. The tasks to which the worker was set became more and more simple. He lost individuality and became, in fact, a mere mechanical appendage which could be easily procured, easily replaced, apparently requiring little consideration.

The development of a spirit of solidarity among workers and their organization which may not only retard production but force issues has caused the manufacturer to take cognizance of the situation and to establish a means of meeting the problems involved. A recent book by Frankel and Fleisher,¹ of the Metropolitan Life Insurance Company, entitled "The Human Factor in Industry," reviews and studies this scheme from the point of view of the man who seeks a finer adjustment of the parts of an extremely complicated machine, summarizes the results of these attempted adjustments, and suggests lines of future activity. There is a general agreement among community, employer, and employee that the fundamental purpose of industry is to produce the greatest possible quantity and the best quality of useful commodities with the least possible cost and effort. It is the problem of the labor administration to make each worker and each hour as effective as possible. The authors touch in turn on the internal problems of hiring and holding; education, industrial and vocational; working hours and conditions; medical care; methods of remuneration; refreshment and recreation.

More and more the employer has to enter into and take cognizance of the external interests of his employees, and, although housing, recreation, educational and health facilities are of great importance, he must always bear in mind that the fundamental demand of the employee is a fair wage. Any substitute for this will fail. What the employer wants is efficient, permanent employees. If the living conditions in a community are such that the payment of fair wages alone will not secure decent living conditions for his employees, economy and justice make him responsible for improving them. In the large city an employer can secure conveniences for his workers by making the best transportation facilities available, having an information service in regard to available accommodations, and perhaps in forming a cooperative store, or facilitating the purchase of homes. His responsibility in the isolated community is greater and so, also are the dangers in the assumption of that responsibility. If the wages are adequate, the employer may soon withdraw his direct efforts, and let the people decide what they want and manage affairs as they think best.

A chapter is devoted to the discussion of insurance, savings, and loans, covering the topics of group sickness, life, fraternal, and accident insurance; the various carriers with their relative advantages and compensations. A discussion of health insurance as a possible approach to the question of sickness, is rather conspicuous by its absence. The question of old age in industry, its extent and causes, and the methods of providing old age insurance through annuities, pensions, and service pensions is outlined. Although it may be conceded that old age is

an industrial problem and industry should be compelled to bear the burden, the difficulties of the scheme seem to outweigh the advantages. Few industries have been willing or able to develop any satisfactory plans. Corporation pension systems provide only for the better class of mechanics and other well paid laborers, while the great mass of common day laborers is not touched. Any pension scheme for employees with one corporation as the unit is unsafe for the group covered if not large nor varied enough. The various investigations tend to show that adequate provision is not made by trade unions or fraternal societies. Insurance is designated by the authors as the means of meeting the situation, but whether that insurance should be compulsory for all adults, for certain groups, or voluntary; whether it should be carried by the state, private insurance companies, or mutual societies, or by all three in competition, is apparently a question for the future to decide. The problems are pointed out but the issues are not faced squarely in the light of future development.

The need for greater total and hourly output and the need for more leisure for recreation will always make efficiency in production a common goal for employer and employee. Labor administration should make industry more effective by making the workers more efficient, and the output for each hour of effort better in quality and greater in quantity. Before the installation of a new system of labor administration there should be a careful preliminary study and analysis of the situation and the approval and understanding of the workers should be gained. The organization and administration of the work itself should be in the hands of persons with technical training, as well as an appreciation of method and purpose. The spirit with which the work is inaugurated and continued, the earnestness of the desire in those who administer it to secure the fullest cooperation of the employees in solving these human problems of production, remain the chief factor in its success. Success awaits the extension of service activities in any industry, if employer and employee are bent only on securing through them increased effectiveness for each individual, and for the business as a whole. With such a concept the old paternalistic approach has no place. Service for the worker becomes solely and frankly a business proposition in which each employee from the president down is interested. The development of any single activity must be carefully considered, its introduction must be such as to promise maximum returns, and its development, administration, and control must bring increasing results.

D. K.

INTERNATIONAL NOMENCLATURE

At the third session of the International Commission for the Decennial Revision of the Nosologic Nomenclature, held in Paris October 11 to 14, certain changes were endorsed in disease classifications. Class one, dealing with epidemic, endemic, and contagious diseases, was divided into two classes, (1) epidemic, endemic, and infectious diseases, and (2) other general diseases. To Class one were transferred, from diseases of the nervous system, the following diseases: acute poliomyelitis, epidemic cerebrospinal meningitis, and lethargic encephalitis. Under influenza a subdivision was made for diseases of glandular origin, and the diseases due to disturbances of nutrition were brought together.

The classification as it now stands contains fifteen classes, divided into 186 numbers, some of which are again subdivided. The new nomenclature can be had by writing to the League of Red Cross Societies, Geneva.

INDUSTRIAL SURGERY AS A SPECIALTY*

BY WILLIAM O'NEILL SHERMAN, M.D., CHIEF SURGEON, CARNEGIE STEEL COMPANY, PITTSBURGH, PA.

INDUSTRIAL surgery as a specialty has been a development of the past ten years. While surgeons and doctors have been associated with industrials for many years, they were never considered as an integral part of the organization of plant or works. The enactment of employers' liability legislations, together with a realization of the responsibility by progressive and humane employers, has brought about a demand in industry for surgeons who have shown their fitness and ability, not only as surgeons, but as executives who have a broad and liberal vision and grasp of the many problems common to the environment and needs of the respective industries. The delay in recognizing and including the surgeon in industrial organizations in the past was partially due to the lack of training and sympathy on the part of the medical profession. It was considered unethical and frowned upon by certain of the profession to be associated with an industrial institution in which the doctor was compensated by salary, though it has become obvious to those familiar with the subject that the only way a surgical or medical organization can be efficiently operated is on a salary basis, dependent upon the time spent and qualifications of the doctor.

One Physician vs. Group Plan

The old plan of contract practice which is followed in certain communities today, in which the doctor, who employs underpaid assistants, is employed by being paid a fixed monthly rate for each employee, is to be condemned. There are certain local conditions, such as isolated mining communities, where this plan is the only practical and efficient one, but in such cases all the doctors should be paid salaries commensurate with their ability. The contracting, or directing doctor, is entitled only to his fair share of the earnings, and not to the lion's share of the collections. We recall incidents where the so-called contract doctor was collecting from twelve to twenty-five thousand dollars annually, paying his young assistants from \$100 to \$125 monthly. As the result of such a policy the employees as well as the doctors and employers were being cheated. In such isolated communities where it is necessary and expedient to organize by collecting a fixed sum from the employees, an attempt should be made to organize along the lines of the group system, something comparable to a modified Mayo clinic. This is being done in many parts of the country and has resulted most satisfactorily to employees, employers and doctors. Local conditions and environment must at all times be considered before proceeding with such an organization.

Much of industrial surgery has been more or less revolutionized as a result of the recent World War. Members are now saved from amputation and lives are saved that formerly would have been lost. The Carrell method of treating wounds and infections, the wax treatment of burns, the mobilization, *i. e.*, free exercise of muscles and joints, of fractures by means of Thomas splints, Jones splints, and Balkan frames, and the reconstruction surgery by means of plastic reconstructive operations, active and passive exercises, electricity and massage, are all applicable to industrial conditions and should be adopted

without further delay and absurd discussion. Many, many lives were needlessly sacrificed, and countless amputations and major operations could have been prevented, had there been some general policy tending to the immediate application of new and modern methods throughout the armies, until such time as better or more improved methods were available. It seems almost inevitable that any change in methods or treatment from the old orthodox methods is due for severe condemnation and criticism on the part of those who know nothing whatever about the subject and those who think they are infallibly wise. It is our duty to accept new ideas when they are conclusively proved. Every real advance meets with such violent opposition that as a result the public fails to gain the benefits of scientific discovery until years after the first introduction. We should not be gullible to everything that is being advocated; however, the unreasonable reactionaries are just as great a menace as the most ignorant.

Excluding certain conditions, there is no excuse today for the so-called infected cases. In the great majority of instances infection is due to carelessness or ignorance on the part of doctors or nurses. In well organized industrial services, infection is almost unknown. In this respect, the industrial surgeon has shown the way to the general surgeon. It is imperative that we use every possible resource to cure our patients within the shortest possible time, with the best possible functional result. Those who complain that certain dressings or apparatus take too much time to apply have no moral right in the medical profession if, in order to save themselves time, they are unwilling to give their patients the service they know to be the very best.

Methods That Shorten Disability

Championier twenty-five years ago advocated the early mobilization, *i. e.*, free exercise of joints and muscles, in the treatment of fractures. His advice was unheeded until the onset of the war, but it is now generally conceded that early mobilization of joints in fractures and infected joints is vitally necessary if early functional result is to be expected. By putting into practice many of the treatments which were demonstrated to be of great value in the war we have been able greatly to shorten convalescence, to reduce the compensation and return the injured workman to his former employment with a saving of 30 to 65 per cent of the time formerly lost in such cases. It is obvious that we should keep uppermost in our minds the necessity of returning the injured to work at the earliest possible date with the least loss of function. Time lost from accidents is a loss to employer as well as employee.

Much can be learned by industrial surgeons by visiting hospitals and industrial organizations where up to date surgery and methods are being practised. Every method should be made to introduce new and improved methods.

The medical schools at Harvard and the University of Cincinnati, recognizing the importance of undergraduate instruction in industrial surgery, medicine, and hygiene, have within the past few years included in their curricula subjects bearing on these specialties. At best they can only give a brief course of instruction to undergraduates and efforts should be made by our medical schools to include jointly the subjects of industrial surgery, medi-

*Read before the American Association of Industrial Physicians and Surgeons in joint session with the Health Section of the National Safety Council, Milwaukee, Wis., September 29, 1920.

cine, and hygiene. It makes no material difference.

The outbreak of the war found us totally unprepared from a military standpoint. We are just as much unprepared medically in industry. We should have a post-graduate course of instruction in some industrial center, such as Chicago or Pittsburgh, where the clinical material is ample for such teaching. There are many positions unfilled today because of the lack of properly trained industrial surgeons and executives.

The Department of Industry of the State of Pennsylvania has recognized the importance and value of joint meetings of industrial doctors and employers to discuss their many mutual problems. These conferences have been of much constructive value and have had a tendency to elevate standards throughout the state. The subjects discussed are germane to industry and are of a character seldom presented at medical meetings.

The recently organized Industrial Section of the American Medical Association has awakened the American College of Surgeons to a full realization of their position. In the near future, we can expect helpful suggestions and constructive recommendations which will be of undoubted value to the profession as a whole as well as to industry. It will have a tendency to elevate the standards and introduce into industry the highest professional talent, and ideals. The large employers of labor are only too eager to accept a constructive and helpful program if it can be conclusively proved to accrue to the advantage of the employee.

It is quite evident that we have only scratched the surface of industrial surgery, medicine, and hygiene. It is imperative that those engaged in this field equip themselves properly to render the very best of service to both employee and employer. On our ability to maintain the fundamental conditions of health in the workmen depends not only the health of a particular group, but in great measure the prevention of debility and proneness to disease in the people as a whole. Those of us who develop sufficient breadth and vision are going to fill a great need. Mechanical, chemical, civil, and electrical engineering have been wonderfully developed during the past fifty years. Human, or medical engineering, as applicable to industry, has been almost lost sight of and has only recently made its presence felt. The opportunities are great and it behooves us to keep pace with the public. Industrial surgery is certain to develop rapidly during the next decade, and we should at all times adjust ourselves to the scientific advances as they are applicable to our work.

Those engaged in this work who are interested chiefly from a monetary standpoint can expect little success and should withdraw and enter some other field. The successful industrial surgeon is the one who loves his work, who receives his chief reward from the satisfaction of work well done and who treats his patients as he himself would like to be treated were positions reversed. Always be frank, honest and sincere with your patients; don't forget that they, too, are human and not a piece of machinery. Such conduct on the part of the physician will gain their confidence, good will and cooperation, and will have a great tendency to bring the surgeon closer to the employer and employees.

KANSAS CITY HAS NEW CLINIC

There has been established at St. Joseph Hospital, Kansas City, under the direction of Dr. J. D. Griffith, chief of the staff of the St. Joseph Hospital, a clinic for the treatment of all diseases. A staff of forty-two physicians will have charge of the clinic.

FLAT FOOT AND EFFICIENCY

There is no more frequent cause for disability and consequent "lay off from duty" in the naval service afloat or ashore than so-called "flat feet," declared Dr. C. F. Painter, Lieutenant, Medical Corps, United States Naval Reserve Forces, in the July issue of the *United States Naval Medical Bulletin*. Some conclusions by Colonel Painter are of particular interest to industrial physicians, especially in the relation of fatigue to flat feet.

The element of fatigue induced by disproportionate amount of standing, declared Colonel Painter, is of more influence than that caused by exercise even to excess. In other words, the ability of a muscle to contract and do its duty under stress is much less when the fatigue comes from unremitting tension than when tension changes constantly, as in walking. It is for this reason that those who change from one sort of duty to another involving a change in the relative amounts of standing and walking and the character of the surfaces upon which the work is done are the ones who break down first under the stress. In civil life it is seen most among those who take up, for example, positions as clerks and are obliged to stand behind counters with comparatively little occasion or opportunity to walk and exercise their leg muscles. The same thing is true of cases seen in naval practice. Men come into the service from all sorts of occupations, are put to strenuous work on decks with small opportunity to get any continued exercise in the way of walking. They are set to drilling without any reference to previous conditions of occupation or training. The normal foot will, in the majority of cases, stand up even under such rapid shifts without showing any tendency to give way. The foot, however, which is not up to standard will not behave as well, and unless carefully handled may go on to a state of considerable disability. In this type of case faulty shoeing or any improper method of poising the body weight over the foot may be the determining factor in causing the symptoms.

After considering various forms and effects of flat feet, Colonel Painter speaks of the care and prevention of the disability as follows:

Much diversity of opinion has been expressed regarding the treatment of flat foot. It seems to me that under conditions where absolute control of the patient is possible there is rarely any necessity for apparatus treatment, and that a period of time under hospital supervision, which should not exceed that ungrudgingly allotted to a case of appendicitis or other major surgical procedures, should straighten out these cases. If proper precautions are observed in regard to muscle-training exercises afterwards, there should be but little liability to relapse. No complicated system of muscle training is required; merely an insistence upon the daily systematic performance of a simple group of exercises accompanied by hot and cold douching of the feet, and massage where it is possible to obtain it.

The cases where plates are necessary are those in which the condition has gone to adhesion formation and have had to be broken up forcibly, or where the conduct of the case cannot be absolutely supervised, or a reasonable amount of rest and attention given.

The following are the exercises which have been found sufficient to restore these cases to functional activity if faithfully followed:

1. Flex foot; extend foot; circumduct foot, alternately and in both directions.
2. Curl toes.
3. Feet parallel, roll up on outer borders.
4. Turn toes in, rise on toes.
5. Foot placed on floor. Keep ball of great toe and the heel on the floor and lift the inner border of foot as much as possible from the floor.
6. Resistive exercises for strengthening the peroneal and posterior tibial as well as the anterior tibial and gastrocnemius groups. The resistance may be manual or by means of spring balances, weight and pulley, or elastic resistance.

The exercises should be done twice per day, from fifteen to thirty or forty times each. After the exercises there should be a short period of hydrotherapy and massage. The exercises should be performed slowly.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

SALIENT POINTS IN THE YEAR'S RECORD

THE year 1920 was marked by no special epoch making advance in the field of public health; but steady and important progress has been made in several directions.

In the field of etiology Noguchi¹ has continued his studies of *Leptospira icteroides* and materially strengthened the hope that a serum may be developed for the treatment of yellow fever by the use of this organism. Wolbach and his associates² have practically completed proof that *Rickettsia prowazekii*—as Da Rocha Lima believed—is a causative agent in typhus fever and have strengthened the hypothesis that another species of *Rickettsia* is the cause of trench fever.

There has been unusual activity in the tuberculosis sector. Krause's³ remarkable series of essays have continued in the *American Review of Tuberculosis* and have materially helped to clarify the complex problems of immunity in this disease. From the statistical side Cummins⁴ has furnished clear and convincing evidence of the rôle played by acquired immunity in determining the mortality from tuberculosis and its age incidence in various communities. Studies on chaulmoogra oil, and its constituents and their specific toxicity for the acid-fast group⁵ are not only of primary importance in connection with leprosy but may prove of significance in connection with tuberculosis as well.

On the engineering side of public health no important advances have been made except the experiments at Sheffield, England, on the oxidation of sewage in the activated sludge process by agitation with paddles instead of by direct aëration with fresh air. If this method proves successful, it should materially reduce the cost of sewage treatment.

In the practical field of public health administration progress has been steady, but not spectacular. The general death rate for the Registration Area, which rose to 18 for the influenza year 1918, fell to the remarkably low level of 12.9 per 1,000 for 1919, while the tuberculosis death rate dropped to an equally notable minimum of 125.6 per 100,000. State reports indicate that 1920 will show a record nearly as good as, or better than 1919. How far this sharp fall in the death rate was due to a selective influence of the influenza epidemic, to the physical fitness produced by military training, to prohibition, or to prosperity, only future statistical studies will

determine. In any case, the result is gratifying. Two events of the year, however, serve to warn us of the necessity of constant vigilance. The fact that plague has gained a substantial foothold in several Texas seaports has caused a vigorous development of the anti-rat program in all our seaboard cities; while the typhoid epidemic at Salem, O., which reached its peak November 1 and comprised 763 cases by November 19, is a lesson as to the danger of underground contamination of gravity pipe lines which waterworks' engineers must take to heart, this epidemic having had its origin in a broken tile pipe through which the city got its water.

Among the most gratifying events of the year was the defeat of the two referendum proposals in California which would have prevented animal experimentation and practically eliminated effective school inspection throughout the state. The fight for these measures was conducted with ample funds and the most reckless appeals to prejudice. The final result is a triumph of American sanity.

The introduction of the New York State Health Center Law⁶ was an event of outstanding importance in the field of sanitary statesmanship, even though the law failed of passage at the spring session. A New York city—Jamestown—has also made a most significant contribution to the sanitary and economic problems of milk supply by the establishment, after a long struggle, of a municipal plant for the pasteurization and distribution of milk.

In Europe, epidemics of typhus have continued to rage, in Poland and the Russian border states, with very limited success in large-scale control. The European nations are rapidly awakening, however, to the importance of public health problems and, particularly in Czecho-Slovakia, developments are to be anticipated in the near future.

The establishment of a Ministry of Health in Great Britain has been signalized by the publication of a notable report by Sir George Newman,⁷ which formulates clearly and simply an inspiring program of public health development. On the continent the League of Red Cross Societies at Geneva has been organized for work under the direction of Dr. R. P. Strong, and its future service in the development of public health work in Europe, particularly along educational lines, should be an important one. The publication of the *International Journal of Public Health*, whose first numbers are admirably edited, and the establishment of an international school of nursing in London are two of the notable achievements of the League during the past year.

MINISTRY OF HEALTH REPORT

THE first annual report of the British Ministry of Health is a very noteworthy document. It simply teems with information, mainly from the standpoint of preventive medicine, as to the health situation in England and Wales.

As only parts of it can be commented on in a brief letter, those will be chosen which appear most likely to interest the readers of MODERN MEDICINE.

It may be as well to state that the report is written under the direction of Sir George Newman, chief Medical Adviser of the Ministry, who contributes an introduction. In the introduction the following definition is given of the duties, functions, and powers of the Ministry. It is described as a new central authority created for the purpose of supervising the health of the people as a whole, and for unifying and simplifying the central agencies working in this behalf. It has taken over existing medical powers and functions, particularly the work of the Local Government Board, and the English and Welsh Insurance Commissions as well as that of the Registrar General. Certain subsidiary public health functions of other departments have also been incorporated, viz., the Board of Control and certain medical duties or responsibilities of the Board of Education, Home Office and Privy Council, with the object not merely of collecting these Agencies from various offices and concentrating them into one, but of welding them together and giving them such new orientation as shall be conducive to the health of the people as a whole.

It is a question of new relationship, focus, and outlook, as well as of collection together; in short, it is a national scheme of preventive medicine, and one that has never been attempted on so vast a scale in any country.

In reviewing the health of the British people, it is pointed out that it has been customary in this country to give chief consideration to changes in population, to the birth and death rates, and to the incidence of infectious diseases. In addition to these categories there must be also included an estimate of general sickness, invalidity, and disablement. The population of England and Wales in 1919, was 36,800,000. The number of births recorded in 1919 was 692,438, including 41,283 illegitimate, yielding a birth rate of 18.5 per 1,000 of the population. In 1903 there were 948,271 births; thus yielding for 1919 was 250,000 less than this highest figure. On the other hand, there were in 1919, in England and Wales, 504,203 deaths, or the equivalent of a death rate of 13.8 per 1,000. The trend of the death rate is steadily downwards, and the decline has taken place at all ages. As regards infant mortality, during the first twenty years of the present century there has been a remarkable fall in the total infant mortality, and recently also in diarrheal diseases. In fact, the decline has been in diarrheal and respiratory diseases, rather than in all causes of death under the age of three months. In England and Wales it may be noted that the incidence of infant mortality falls chiefly in the first three months, and in the first week of the first three months; that it is higher in urban than rural areas; higher in the North than the South; that it is higher among illegitimate children; that its incidence is dependent not upon density of population, but upon local and domestic conditions, characteristic of limited industrial areas, or social classes of the community; that it is high among the poor, and low among a better social class; that the three chief causes of death in infancy are developmental conditions, immaturity, prematurity, debility, diarrheal disease, and respiratory disease; that

since 1901-1910 there has been a significant decline affecting the whole of the first year, but particularly in regard to deaths due to diarrheal disease, then to respiratory disease, and only much less so in respect to developmental disease. Speaking generally, it may be said that the developmental conditions cause about 30 per cent, and the respiratory, diarrheal and other infective conditions, about 40 per cent of the total infant deaths. The number of still-births notified in 1918 was 19,757, or approximately 3 per cent of the live births. The mortality of illegitimately born infants is principally due to death on the first day, syphilis or to maternal ill health and to neglect leading to diarrhea, prematurity, and atrophy.

It is obvious that the health of the mother and child is the primary and essential step to be taken to insure or rather to safeguard the health of a nation. The Ministry of Health fully recognizes the importance of the matter, and among the measures taken in this direction is a scheme of maternity and child welfare which has now been inaugurated in every county and county-borough, and in many of the larger urban districts. In many areas, the midwifery service is being reorganized and brought into closer association with other forms of maternity and infant health service.

Attention is drawn to the fact that the physical care of maternity, infancy, and childhood is now—for the first time—supervised by one department of State, and the result should be a single, unified, and continuous supervision from birth upwards.

As said before, the report is a perfect mine of valuable information regarding the health conditions of England and Wales, and also of some of the means proposed to prevent disease.

It may be argued, and perhaps rightly to some extent, that the schemes sketched in the report are too ambitious and idealistic, but it is best to aim high; and idealism in this material age is a rift in the clouds that obscure the light of progress.

In any event, the report itself gives such an excellent bird's eye view of the English people and of other matters relating to preventive medicine, that it is a document which no one interested in such matters should pass by.

LONDON CORRESPONDENT.

COLORADO PSYCHOPATHIC HOSPITAL

As a result of the recent election, Colorado is assured of a psychopathic hospital and of sufficient funds to erect and maintain it. There will be provided a laboratory as well as a hospital and such service as will assure that the "curable insane" will be cared for. The success of this measure is the result of a well organized campaign following very closely the suggestions of the National Committee on Mental Hygiene. It was impressed upon the people, states the *Journal-Lancet*, that the main object of the state and of the individual should be the prevention of insanity. The intelligent interest of the public was aroused by propaganda as to the urgency of the problem. The importance of prompt care and treatment of incipient cases was brought out, the duty of the state to these unfortunates was emphasized, and the public was made acquainted with the appropriation of funds necessary for the project. The whole proceeding stands out as an example of what may be accomplished by intelligently organized effort.

I consider the establishment of health and right living habits as being the most important factor in education.—Dr. P. H. Claxton.

VENEREAL DISEASES—PHYSICIAN'S RESPONSIBILITY FOR THEIR CONTROL

By MILLARD KNOWLTON, M.D., C.P.H., REGIONAL CONSULTANT, UNITED STATES PUBLIC HEALTH SERVICE, NORTH CAROLINA STATE BOARD OF HEALTH, RALEIGH, N. C.

A SENSE of public responsibility for the venereal disease problem is one of the by-products of the war. When faced with the necessity for utilizing the manpower of the nation to the limit in combat with a first class military power, America soon recognized venereal disease as the most serious communicable disease menace to its military strength. Medical men have not forgotten that 5.4 per cent of the second million men called to arms had venereal disease when they reached camp. Thus the war brought the venereal disease problem to the front as a public problem.

Even in war time the venereal disease problem is essentially and fundamentally a civilian health problem. Five out of six of the soldiers suffering from venereal diseases were infected before enlistment. The others became infected by contact with the civilian population. Adequate preparation for the defense of the nation against future aggression requires careful attention to the venereal disease problem by the civilian communities. Any problem so closely related to the defense of the nation is a public problem.

A Menace to Present and Future

Inasmuch as gonorrhea is looked upon as the greatest sterilizer, and syphilis as the greatest abortifacient, it behooves the people to take measures against the ravages of these diseases in order to maintain a birth rate that will give the best assurance for the future of the nation. An excess of births over deaths is necessary if a nation is to grow strong. France is now suffering because of a low birth rate. Any factor that affects the birth rate as does venereal disease is a vital public problem.

During the war it was found that in a large munition plant employing 10,000 workmen, 68 per cent of the workers on the non-effective list each day were listed because of venereal diseases. Production among those so infected was found to be 33 per cent below normal. Facilities for treatment were provided and 2,000 employees were treated during the year. Every man's output returned to normal after treatment was concluded and the man returned to health. The company estimated that the work was worth at least \$150,000 per year in increased production. At this time of high prices whatever tends to retard production is a public problem.

Potent Factor in Dependency

Another factor of immediate public concern because it involves the expenditure of public funds is the relation of venereal disease to dependency and defectiveness. How much of the state and local expenditures for the care and maintenance of dependents and defectives have been made necessary by venereal disease cannot be said. That such expenditure is far beyond the cost of prevention must be apparent to anyone who will give the matter a second thought. Indeed, when we consider the public charges in the alms houses and other institutions whose lameness, epilepsy, blindness, feeble-mindedness, insanity, or other cause of dependency is due to venereal disease, we may well believe that the state would profit by taking measures to prevent these diseases, as did the munition plant, by

providing treatment for infected persons. Thus it appears that when viewed from any angle the venereal disease problem is a public problem. Even from a clinical point of view, pay for the treatment of such diseases among indigents must come from the public purse.

Remedy to Be Applied at Source

Owing to the complicated and intricate character of the venereal disease problem, the remedy has not been one of easy attainment. Experience has led to the direction of the campaign against venereal diseases along three general lines:

(1) Educational measures for the dissemination of information are regarded as fundamental for any kind of advancement under a popular form of government.

(2) It is now almost universally recognized that effective measures against venereal disease will include the repression of prostitution, which is the great source of infection. Prostitution is no longer to be regarded as a fixed part of the social structure or even as a "necessary" evil. As a commercialized institution its doom is sealed. The public will not permit a return to the old conditions.

(3) That part of the attack against venereal disease which is of most interest to physicians is treatment. It is by proper treatment that infected persons are rendered non-infectious. Thus treatment is a matter of public concern and the physician who properly treats a case of venereal disease performs an important public service.

So much by way of introduction. I wish to use the rest of the time allotted to this paper in a discussion of the problem of treatment. I have no information or suggestions to offer concerning the methods of treatment. I wish merely to make a plea for better treatment, and to suggest a plan whereby I believe that better treatment may be provided for patients in remote communities.

The Physician's Responsibility

No one but a physician is qualified to treat venereal disease properly. This is one branch of the healing art in which physicians have a monopoly. The osteopath, the chiropractor, and the Christian Scientist are constrained to withdraw from the field and leave the medical man in full control. This monopoly presupposes a responsibility and it is for a keener sense of responsibility and a better preparation for the discharge of their full duties that I now wish to plead with physicians.

Medical men are disposed to take venereal diseases somewhat more seriously than formerly, but many physicians still do not care to treat such cases. To be sure, there are unpleasant features about this kind of work; but the physician's responsibility cannot be fully discharged by giving indifferent or careless treatment. The physician owes it to both his patient and the public to see that the best possible treatment is given.

All physicians will agree that patients should not attempt to treat themselves and should not rely upon drugstore treatment or treatment by quackery. In propaganda designed to turn patients away from self-treatment, the counter prescriber, and the quack, it is constantly urged that proper treatment can be given only by a quali-

fied physician who can examine the patient carefully in order to determine what treatment is needed. Sometimes the busy doctor makes an unfavorable impression upon the patient by failure to live up to our promises concerning a careful examination. A case in point is that of a North Carolina woman who was infected with gonorrhea by her husband upon his return from the Army. Before treatment was completed it became necessary for her to move to another city where she sought to continue treatment under a physician's care. Her experiences in that connection are given in the following extracts from a letter recently received in our office:

I have tried three doctors, and the one who was most recommended, Dr ———, merely asked me what treatment the doctor in ——— had given me, and told me to continue that treatment. He did not say for how long, nor did he offer to make an examination. According to your pamphlet and letter such indifferent advice is unsatisfactory. This doctor did not even ask me to come to see him again. He acted as if he were wholly incompetent to give advice in this case. . . . I am very much concerned about my condition and I want to be helped. I have already spent a large sum of money for medicines, doctors advice, etc., and a great deal of time in treating myself, and I think I am entitled to some results for my outlay of time and money. Why cannot the law require doctors to be more competent? I think any doctor as negligent as the one I have mentioned should be reportable by the patient. A case like this is too serious for a doctor to be careless about.

The foregoing statement by a woman of education and refinement merits serious consideration by physicians. If the medical profession is to maintain its prestige with the people and continue to enjoy the fullest public confidence, it is highly important that physicians meet the increasing demands of a more fully educated public.

In meeting these requirements only two courses are open to a physician when a venereal disease patient applies for treatment. These are either to give the best possible treatment himself or refer the patient to a physician who will give the best possible treatment according to modern methods. Remembering that each uncured case of venereal disease is a source of danger to others, the physician can perform his full duty to himself, his patient, and the public only by pursuing one or the other of these courses.

The public interest requires that all patients suffering from venereal disease be properly treated no matter what their race, color, or social position may be. Venereal diseases, like other communicable diseases, know no racial boundaries. Where different races of mankind are intermingled it is to the interest of each race, as a matter of racial self-preservation if from no higher motive, to have venereal diseases properly treated in members of the other race. Physicians have it within their power to see that proper treatment is given to all sufferers from venereal disease.

I am not asking physicians to work without remuneration. Most venereal patients can afford to pay at least a reasonable fee for treatment. In the few instances where a person suffering from venereal disease in communicable form is really indigent, it is simply a matter of self-protection for a community to provide treatment at public expense. State Boards of Health will provide arsphenamine free for the treatment of indigent syphilitics who are infectious, provided the community or a big-hearted doctor will see that the drug is properly administered. In the larger communities the most convenient way of providing treatment at public expense is by means of clinics. In the smaller communities some modification of the clinic arrangement may be necessary.

Each physician is urged either to give the best possible

treatment or to refer his cases. The question may be asked, to whom the cases may be referred. It is realized, of course, that only the larger cities can support specialists. In rural states where only a small percentage of its population live in or near the larger cities, to the end that rural medical service may be improved, it is proposed that the medical men of each community provide at least partial specialization in medical service to that community. This will be possible through concerted action. As a first step, let the physicians in each county get together, talk over the proposition and select from their number one who is willing to make special preparation by study and equipment for the proper treatment of venereal diseases. Of course, he cannot hope to limit his practice to this line in a small community, but by partial specialization he can become an authority on the matter for his own community to whom patients may be referred or who may be called in consultation in difficult cases. The man who thus qualifies himself for the better treatment of venereal diseases should be selected by the board of county commissioners to treat indigent patients. He should be recognized by the medical profession of the community in such measure as to make worth while his expenditures in time and money for special training and equipment.

Partial Specialization Proposed

The plan here proposed would result in advantage to both the medical profession and the public. Thus it would accord with a principle that is now happily appearing more clearly in the vision of far seeing medical men. This principle is that the ultimate interests of the medical profession are parallel to the best interests of the public in medical matters. While recognizing the fact that public interests are paramount to those of any class or group, medical men will do well to remember that the doctor serves himself best by serving others.

The gist of the whole matter is that the level of medical practice with respect to the treatment of venereal diseases should be raised to as high a point as possible in all communities of the state. This requires specialization which comes as a natural process in larger communities. In smaller communities the same end can be reached, in lesser degree perhaps, by a process of partial specialization encouraged and stimulated by the medical profession. It falls to the lot of medical men to prevent the spread of venereal diseases by the proper treatment of existing cases. For the best results, united and cooperative efforts for encouraging specialization are required.

The matter is placed in the hands of the medical men in full confidence that they will rise to the opportunity for public service and take active measures to provide better treatment for venereal disease cases in all parts of the country. Let me urge again that united effort and cooperation are necessary. If we doctors do not hang together, the public may give us a chance to hang separately.

MORE DENTAL CLINICS NEEDED

Though the Department of Health of New York City maintains eight dental clinics, more are needed, according to their recent report. The Bureau of Child Hygiene has concentrated its activity largely upon preventive dental work as far as possible.

The personnel of these clinics consists of one supervising dentist, nine dentists and eight nurses. The supervising dentist and dentists are part time officers, serving approximately three and one-half hours daily, from 9 a. m. to 12:30 p. m. The nurse is a full-time employee, with hours from 9 a. m. to 4:30 p. m.

GROUP CONSULTATION CLINIC

By EDMUND C. BODDY, M.D., State Department of Health, Albany, N. Y.

FULLY aware of the difficulties under which the practitioners in the less thickly settled communities are working because of their inability to secure the aids rendered by well equipped diagnostic laboratories, x-ray plants, and other opportunities for consultation with men of special training along diagnostic lines for their difficult or obscure cases, the New York State Department of Health, in cooperation with the State Department of Education, the State Hospital Commission, the State Commission for Mental Defectives, the State Charities Aid Association, and the American Red Cross, have placed in operation a plan whereby a very material aid may be rendered to the medical practitioners in the rural sections of New York state through the Group Consultation Clinic. This group of medical consultants is so constituted as to cover practically the whole field of the practice of medicine and surgery. It consists of a Division of Pediatrics, a Division of Orthopedic Surgery, a Division of Diseases of the Chest, a Division of Diseases of Adult Life, a Division of Neurology and Psychiatry, a Division of Mental Defectives, a Division of Surgery and Gynecology, a Venereal Disease Division, and a Division of Oral Surgery together with a well equipped field diagnostic laboratory and an x-ray department. These various divisions are represented by thoroughly trained medical men who so cooperate in their examination of patients that patients admitted to the clinic may be referred from one division to another as their condition may indicate and an expression of an opinion as to the diagnosis may be obtained from each division, together with whatever laboratory and x-ray examinations may be necessary to complete the diagnosis. The clinic accepts only those patients for examination who are referred by physicians. It has been found that a greater degree of service can be rendered and the cooperation of the physician assured, if this plan is rigidly observed. As the clinic is being conducted at the present time it not only confines its services to those patients who are referred by physicians but has done away with preclinic publicity, thus still further limiting the numbers who might be attracted by publicity and importune their physicians for cards of admission.

Modus Operandi

The territory covered by the clinic has been an entire county and, under the direction of a supervising nurse, every practising physician has been visited by clinic nurses and invited to refer to the clinic all patients on whose case he may desire a consultation. The nurse further offers her services in calling on the patient, arranging for specimens to be submitted to the laboratory, the Laboratory Division being sent on, prepared to do work a week or ten days before the opening of the clinic. The transportation of the patient to the clinic is arranged for by the nurse, who also cheerfully performs any other service that the attending physician may request. No patient is ever visited by the nurse except with the consent of the attending physician.

The director of the clinic also calls on the physicians, explaining the object and scope of the work. He presents the physician with blank history sheets, requesting him to prepare a history of the cases on which he may wish consultation, setting forth any unusual conditions that they may present, and inviting him to make use of the laboratory and x-ray service as the needs of his practice may demand. These history sheets, together with the

request for laboratory work, etc., are collected by the nurse at the time of her visit or brought in by the physician himself at the time the patients present themselves for examination. The family physician is invited and urged to accompany his patients to the clinic and to be present and confer with the various consultants at the time of examination of their patients, when the case can be talked over and discussed by the attending physician and consultants together.

Emphasize Unusual Cases

In the evening following the clinic a meeting of the clinic consultants and the attending physicians is arranged for, at which time the more interesting and unusual cases are taken up and discussed, the family physician presenting the history of the case and outlining the course up to the time the patient was admitted to the clinic, and the various consultants who have seen the case reviewing their findings, with the addition of any necessary information brought out by their examination or the laboratory reports.

After the consultant in the original division to which the patient was at first admitted has reviewed the opinions of the consultants in the various other divisions to which the patient may have been referred and has had a report from the diagnostic laboratory on specimens submitted or an interpretation of an x-ray plate, he makes up the clinic findings, or impressions, or a diagnosis; when these, together with the history of the patient, have been recorded, a complete report is sent to the physician who referred the patient, including the recommendations of the consultants as to further study or treatment of the case; thus the same professional ethical relation is observed as maintains between physician and consultant in ordinary practice.

We append a statement of the number of patients examined and referred to the different divisions at the recent clinic held in Walton, N. Y.

EDMUND C. BODDY, M.D.,
Director of Clinic.

Roster of Consultants

Below is given the Roster of Consultants who attended the Group Consultation Clinic, for Delaware County, held at Walton High School, Walton, N. Y., Nov. 11-12, 1920.

Pediatrics.—Dr. H. L. K. Shaw, clinical professor of diseases of children, Medical College; president American Child Hygiene Association; and Dr. Edith Michaels, supervisor of Child Hygiene Center, New York State Department of Health.

Orthopedic Surgery.—Dr. Leroy W. Hubbard, orthopedic surgeon, State Department of Health.

Diseases of Chest.—Dr. Malcolm F. Lent, director, Division of Tuberculosis, New York State Department of Health; and Dr. Frank MacSorley, supervisor, Tubercu-

losis Hospitals, New York State Department of Health.

Diseases of Chest.—Dr. Joseph P. O'Brien, instructor clinical medicine, Albany Medical College.

Diseases of Adult Life.—Dr. L. W. Gorham, clinical professor of medicine, Albany Medical College; and Dr. Henry Viets, Albany Hospital, Albany, N. Y.

Neurology and Psychiatry.—Dr. Mary F. Brew, assistant physician, Binghamton State Hospital.

Mental Defectives.—Dr. Earl W. Fuller, psychiatrist, Rome State Custodial Asylum.

Surgery and Gynecology.—Dr. Arthur Stein, clinical professor of surgery, Albany Medical College.

Veneral Diseases.—Dr. Edward H. Marsh, consultant, Bureau of Venereal Diseases, New York State Department of Health.

Diagnostic Laboratory.—F. Constance Stewart, bacteriologist, State Laboratory; and Francis Constable, laboratory assistant, State Laboratory Division.

X-Ray Department.—Dr. William P. Howard, assistant attending orthopedist and radiographer, Albany Hospital.

PUTTING THE EX-CONSUMPTIVE BACK ON THE JOB

By GODIAS J. DROLET, MANAGING EDITOR, BULLETIN NEW YORK TUBERCULOSIS ASSOCIATION, INC.
NEW YORK CITY.

THE all too frequent recurrence of tuberculosis, among those whose disease has been apparently arrested by sanatorium or other treatment, has long been a problem calling for solution. The commonest cause of such relapses has been the return from ideal sanatorium life to the same unfavorable working and living conditions under which the disease first started. The sudden change from absolute rest to a full day's work—without a hardening process—is almost equally dangerous. The situation must be met by the gradual utilization of occupational therapy and vocational training, at the sanatorium in the country, followed in town by industrial rehabilitation at a sanitary workshop and by improvement of home conditions.

The Federal Board for Vocational Education, having a large number of ex-service men suffering and recovering from tuberculosis, and recognizing the above facts, proposed to the National Tuberculosis Association and the New York Tuberculosis Association that a workshop for such industrial rehabilitation be established in New York City.

Model Workshop Established

The New York Tuberculosis Association, after preliminary investigation of suitable trades and the best location,

Students in watch repair department of the Reco Manufacturing Company, the model workshop established by the New York Tuberculosis Association.

opened on June 15, 1920, a model workshop in Long Island City for the training, under ideal sanitary conditions, of arrested cases of tuberculosis. It is incorporated under the name of the Reco Manufacturing Company, and is

under the direction of an active committee of public spirited business men, headed by Mr. Fred M. Stein, who established some years ago the Altro Shop, the first successful workshop of this kind for the needlework trades.

The shop has now been running five months. It is situated in the newly developed manufacturing section of Long Island City, in the Borough of Queens. The building is new, has light and air on all sides, is up to date in every respect, and is within five minutes walk of the subway from Manhattan. The plant is on the third and highest floor of the building. The workrooms have large windows on all sides and there is a maximum of air and sunlight for its occupants. The shop is equipped with hygienic and sanitary fixtures. Here the handicapped worker may gradually be trained to a trade and be conditioned to resume regular work.

Admission Requirements

At present only men with arrested or quiescent tuberculosis and negative sputum are received by the Reco Manufacturing Company. The men now under training are largely ex-service men, but civilians who are suitable patients and anxious to take up any of these trades will be accepted if they are prepared to spend the full period of apprenticeship. They should apply or be referred to the Manhattan Office, at 10 East Thirty-ninth Street, at 9 a. m., daily, except Sunday. Properly qualified visitors are always welcome and arrangements for such visits will be made on request.

Medical and Social Supervision

All applicants are subjected to a thorough medical examination before admission. Close and exhaustive histories of each patient are taken and the effects of the work carefully noted; but, it is a workshop and not a sanatorium, rest camp or health school. Care is taken that the medical and social work, while thorough, is not obtrusive. All examinations are made in Manhattan at the offices of the New York Tuberculosis Association. After a man is admitted to the shop and has started training, he is re-examined at the end of the first week and later once a month to determine the effects of the work. If his condition is at all questionable he returns oftener. In case of a relapse, men are returned to the sanatoriums or hospitals for proper care. Close supervision is kept of all men under training by means of these periodic examinations, and also by the trained nurse, who is at the shop several hours daily and takes temperature and weight of each man weekly.

The amount of work that each man is first allowed to do, as well as any increase of it, are specifically prescribed by the medical officer. A first aid kit is kept at hand;

the nurse's room has a couch and emergency facilities in case of need.

It is intended that the shop be like any other well conducted factory, with the added fundamentals of teaching non-injurious, well paying trades, by part or full time training under strict medical supervision, and under the best obtainable hygienic surroundings. A cafeteria lunch-room has been installed and nourishing meals are served at cost. A rest room is provided on the roof, pro-

The jewelry class of the Reo Manufacturing Company. This is a workshop and not a sanatorium, rest camp, or health school. The medical and social work, while thorough, is never obtrusive.

tested and furnished with reclining chairs, tables and reading matter. The men are encouraged to rest after their lunch and work periods.

The home conditions of the men receive equal attention. Much of the good work may be undone at the home, where bad conditions beyond the patient's capacity to remedy may be present. A trained social worker investigates and visits regularly the home of each man. The benefit of her experience and advice is freely given; the best use of the rooms and resources available are pointed out. Family cares and worries are cheerfully shared; children in need of building up are cared for; the advice of the physician is emphasized and followed up.

Trades Taught

The trades selected to be taught at the shop are watch repairing, jewelry manufacturing and cabinet making; these were chosen only after careful investigation. They are deemed most desirable because not injurious to the lungs nor especially fatiguing. Workmen in these trades are very well paid and there is a great demand for men skilled in these particular occupations. The instruction is carried out by experienced men who are experts in their respective trades. According to conservative experience, the present wages men may earn in these trades are from forty to seventy-five dollars a week.

When the students in the shop have gained enough skill to do marketable work they are paid wages on a piece-work basis. The skill that some of the men have developed has been surprising; without any previous mechanical experience, some have become proficient enough to make saleable articles within two and a half months on only part time training.

Ideals in View

It is the intention to make the city model workshop the last step in the training and treatment of the tuber-

culous. Schools for pre-vocational training in certain sanatoriums (Loomis, Otisville and Gaylord Farm) are conducted by the New York Tuberculosis Association, where preliminary instruction is given to the sanatorium patient and he is prepared for transfer to the workshop as soon as his physical condition warrants. In this way the harmful gap of uncertainty following discharge is bridged. A record of his work at the sanatorium is kept and forwarded to the workshop. This pre-vocational training decreases the amount of time a patient will have to stay in the sanatorium, through the curative effect that it will have on his disease, provided he is interested in the trade. It also shortens his time at the shop because he enters with a grounding in his trade, experience with the special tools required, and is therefore ready for advanced instruction and will begin receiving wages all the sooner.

It is the aim gradually to increase the working hours of the man with arrested tuberculosis until he can do a full day's work; to teach him a well paid trade, keeping him all the while under medical observation until his ability and physical condition warrant discharge; finally, to find him a suitable position. Thus trained, hardened and re-established in life, his chances of again falling a victim to tuberculosis will be minimized, and he can take his place in the community as a healthy, self-respecting, self-supporting citizen.

Christmas Seals Support Workshop

While the enterprise will eventually be self-supporting through the sale of manufactured articles, and while the tuition fees from the Federal Board of Vocational Education give some support, yet the initial cost and overhead charges have been and will be considerable. These are borne by the New York Tuberculosis Association, which in turn is supported by the Annual Christmas Seal Campaign.

The cabinet making department of the model workshop. The shop is like any other well conducted factory with the added fundamentals of teaching non-injurious, well paying trades.

PHYSICAL EXAMINATION OF SERVICE MEN

The Rochester, Minn., local post of the American Legion at a recent meeting unanimously favored a plan for the semi-annual examination of former service men in order to keep them physically fit. The plan recommends itself for general adoption in the Legion. The *Journal-Lancet*, in commenting upon the matter, suggests that physicians outside the Legion will do the work free.

CLEVELAND HOSPITAL AND HEALTH SURVEY

A popular summary is in our hands of the Cleveland Hospital and Health Survey which was made under the direction of Dr. Haven Emerson. Under ten subdivisions the results are brought together in an effort to formulate a practical working program for extension of health work in Cleveland.

Cleveland has been outstanding in her progressive attitude toward community responsibilities and health matters, and that so many deficiencies are emphasized in the report may well be taken as indicative of a like condition in other parts of the country. The territory is too large, according to the report, for the Bureau of Communicable Diseases to oversee properly. The \$7,000 a year spent on vital statistics is wasted because of lack of leadership. A city medical examiner is recommended to replace the office of coroner with its political connections. Provisions for crippled children are lamentably inadequate, and special attention is called to the startling fact that more deaths in Ohio are due to heart disease than to any other single cause.

The weakest spot in the school medical plan of Cleveland seems to be in the lack of supervision. A need is expressed for a standardized hygiene outline and for the bringing together of the Department of Physical Training and the Department of Medical Inspection which, oddly enough, are at the present time absolutely unrelated.

Cleveland is admirably equipped with legislation for the prevention of tuberculosis. It is pointed out that the factories should do more in detecting tuberculosis in its early stages and that the need of more nurses is evident.

Provision for mental patients is adjudged the poorest in the United States, their care being more a matter of law than of medicine. The remedy lies first in an improvement of archaic laws. The best work being done in this field is that being undertaken by the Bureau of Juvenile Research.

In the field of industrial medical service, emphasis is placed upon the need of standardization and a remedy for the deplorable scarcity of records in factories. Especially is the need felt in Cleveland for an industrial hospital, or for such reservation in other hospitals for emergencies as will take care of urgent cases which now must be taken to one hospital after another before room can be found for them.

It is mentioned that the status of women in mercantile establishments in Cleveland is of the highest order.

Of the children of Cleveland of seventeen years of age 75 per cent are already at work and many have been working for two or three years, their passage into industry being made without special guidance. The difficulties of supervision are indicated by the fact that each truant officer in Cleveland has 10,000 children under his supervision.

Cleveland leads in her public health nursing, thanks to her unique Central Committee on Public Nursing. No other city has ventured to adopt a generalized municipal system. Thirty-six plants in Cleveland provide industrial nursing.

The hospitals and dispensaries of Cleveland enable the care of only 10 per cent of the 20,000 people who are ill at any one time, an average far below that of other large cities. Recommendations are made in regard to the government and staffing of hospitals.

The problem of transporting patients to hospitals has received almost no attention in Cleveland. Part of the inadequacy of hospitals may be charged to the fact that

no institutional accommodation is provided for convalescents and 87½ per cent of the patients who leave the hospitals go home to unfavorable surroundings. The hospitals and dispensaries of Cleveland were "planted, not planned. Each has grown without any relation to the other and the time has come when a community plan should be realized, so that the present neglect in the care of children, and of eye, ear and nose diseases will be impossible."

Special commendation is given to the good work accomplished by the Cleveland Hospital Council, and an encouraging note is sounded in the clarity of vision of the spirit of cooperation evinced in the principal investigation.

THE WHOLE STORY OF ONE EPIDEMIC

Those who read the brief dispatches from Salem, O., which were carried in nearly every newspaper in America, noticed wearily that some hundreds of people were suffering from typhoid fever and that in the course of a couple of weeks fifty of them died. Then came later bulletins that the city of 12,000 in eastern Ohio, a busy little manufacturing town, just out of the district of the great Mahoning Valley steel mills and right upon the edge of the coal fields, was recovering from the epidemic that multiplied the monthly death rate by three and reduced to danger of death one person in every ten.

The small news had but little portion of day to day interest and was dismissed as one of the incidents of national life. Few people asked themselves what it cost or the cost of prevention of such epidemics. For the benefit of Salem, O., and countless other Salems all over the United States, some larger and some smaller than the little city in eastern Ohio, the Ohio Department of Health has furnished figures on what the epidemic did to the common purse.

It took the amount of the average income of upwards of five hundred men in peace time. It took four times what the city collects in taxes for all purposes in a year, and it took away at one swoop nearly 4 per cent of the property of the city, all this in addition to the loss in suffering, in tears and in grief. The losses here given are calculated as cold economic losses, without sentiment of any kind.

State appropriation	\$ 5,000
Red Cross appropriation.....	50,000
Municipal appropriation.....	15,000
Private expenditure (including medical service and drugs, 850 cases at \$50 each).....	42,500
Private expenditure—nursing service, 200 cases at \$100 each.....	20,000
Loss of time by wage earners (one-third of cases, weeks each, at \$5 per day).....	60,000
Funeral expenses, 50 deaths at \$150 each.....	7,500
Value of lives lost, employing the basis of an average of \$4,000 for each one.....	200,000
Business losses (due to lowered earning power and to avoidance of city by persons from outside) estimated at.....	50,000
Total	\$450,000

The infection came from a broken tile pipe through which the city got its water. It was laid before there was state regulation of waterworks systems. In putting down this tile pipe, instead of iron pipe, the city made a saving of \$1,500. It had another saving in that it had spent nothing for bacteriological supervision of water supply, which would have cost \$1,000 for each year. The total saving of \$2,500 is counted against the loss of \$450,000 as calculated by the Board of Health experts. The matter is reported as a concrete illustration of the value of such "economies."

THE RELATIONS OF PHYSICAL PROPORTIONS TO GENERAL HEALTH

By G. J. WARNSHUIS, M.D., MARMARTH, N. D.

THESE observations were made some time ago but as the series is rather small it is with considerable hesitation that the inferences drawn are cited as definite conclusions. Nevertheless, they are so much in accord with subsequent general experience that we may confidently assert that further tabulations will bear them out. This report is presented, therefore, not with the hope that it will be accepted without dispute but in order that these conclusions may at least act as suggestions for further investigations.

Evidence of Constitutional Inferiority

In the formal physical examinations required by insurance companies and other corporations it has always been customary to record the chest and abdominal measurements of the subject as well as the height and weight. Outside of the knowledge this procedure affords of the general state of nutrition, the question arises whether such data have any other significance in indicating the state of health of the individual or if any other measurements might be of equal if not greater importance.

Authors on the subject of physical diagnosis are given to repeating that a long waist is an evidence of constitutional inferiority and different methods of measurement have been invented for describing this proportion, although why or how this conclusion was reached has never been elucidated. Having a rather long waist myself, which has never given me any particular trouble except for the annoyance of being constantly on the guard to keep a proper length of shirt-tail within my trousers, caused me to feel a natural skepticism toward this opinion. On the other hand, if there be any truth in this theory, such measurements should be of value to industrial corporations in determining the physical fitness of applicants for employment.

The total number of persons examined in this series was 309. A study was made of some four hundred other examination records, but the results in respect to chest measure varied so markedly from this series that they were disregarded as inaccurate. Of these 309 the length of trunk from upper border of sternum to upper border of pubis was measured in 160 and compared with those showing length of sternum and total height from head to foot. The length of sternum varied as much in those with short or normal bodies as it did in those with bodies more than twenty-two inches in length. The average body length was 21.3 inches. There were nineteen with bodies more than twenty-two inches long, and all of these showed an increase in the length of chest above the average. The average length of sternum was 6.2 inches and yet there were only five who had a sternum less than six inches long.* All five of these had a corresponding decrease in the length of the body and, instead of being under weight, they were normal or above, and were well developed in every way. It is true that a long sternum is often associated with a short body, but none of this series showed evidence of being more robust than the others. In fact, the opposite was more often true, and

the only conclusion that can be drawn in reference to the length of the sternum is that it is subject to independent variation apart from variations in the length of the anterior surface of the body, and such variations seldom produce anything more than an insignificant increase in the proportionate length of the waist, but may often decrease it below the average.

It was interesting to note that out of thirty-five men who were more than seventy inches tall, more than two-thirds, or 72 per cent, had bodies no more than normal in length; 80 per cent of the men who were less than 68 inches tall had bodies of average or greater than average length. In two the bodies were longer than normal. This certainly justifies the conclusion that the tendency to variation in the length of the long bones is far greater, and, also, that the variation in their length is not influenced by the same factors that cause a variation in the length of the trunk. Such selective variations can only be explained by pre-supposing trophic nerve centers as it is absurd to assume that such hereditary variations could be transmitted by a hormone that reacted with the substance of long bones and not with those of the trunk. We have here important evidence that the nervous system exerts a direct control over the growth and shape of the body tissues.

Correlations Are Drawn

My work as examining physician for a certain corporation, as well as through general experience, had early brought out the correlation that individuals with poorly developed chests and narrow shoulders show a delicacy of health and a heightened susceptibility to the effects of such conditions as chronic tonsilitis, pyorrhea, and other organic disturbances which was in direct proportion to the size of the chest. On the other hand, men of large frame often exhibited the most advanced forms of pyorrhea, tonsilitis, etc., without much apparent loss in body vigor, an observation decidedly confirmed by the study of the chest measurements of these 160 men. In order to determine within what limits such variations in size may be regarded as normal, the study was made to include some 309 cases.

The average chest measurement of these, taken at forceful expiration, was 34.63 inches. In 68 the chest measure ranged from 34 to 34.57 inches; 78 were included in the group of 33.5 to 34 inches; and 29 were between 33 and 33.5. Below 33, however, there were only 36, or 11 per cent. As the measurements 33 to 34.5 included 110, or 75 per cent of the total below 34.6, it is fairly conservative to consider any variation below that as sub-normal, especially as the greater number of them were above 33.5, and 89 per cent of the total number were above 33 inches.

Taking 33, then, as the arbitrary standard, one has only to inspect this class of 36 below the line to realize with startling force that there is plenty of reason for considering them defective in respects other than in their shallow chests. Without a single exception they represent persons considerably below normal efficiency. Above thirty-three inches this universal deficiency does not hold true and in this group there are a number of individuals with chest measurements of 33 to 33.5 who are of normal

1. Wiggers: *The Circulation in Health and Disease*.

*Piersol's *Anatomy* gives 6.56 inches; Streinch gives 6.42 in. This speaks favorably for the accuracy of the measurements reported in this study.

weight and vigor. Below thirty-three, however, it is as if we have crossed a barrier behind which healthy vigor and robust vitality is impossible. As a single group they would present a most sorry array, a huge delight for a student in physical diagnosis. The average weight for the group was 140.02 pounds. Seventeen were stunted an inch or more below the normal height; eight of the thirty-six had enlarged tonsils, and were under weight; nine had pyorrhea or dental caries; three exhibited heart disease in some form. One was tuberculous, another had a hernia. All but twelve had at the time, or gave a history of some serious ailment, and only two weighed more than 150 pounds. Of these two, one weighed 155, the other 165 pounds, and both were more than seventy inches tall, so this was no favorable degree of nutrition considering their heights. Comparing their state of nutrition with those whose chest measure was thirty-three inches or more, only 38 of the 273 weighed less than 150 pounds. This does not prove that poor nutrition and disease are impossible to those who have chest measurements of more than thirty-three inches, but it does demonstrate that the incidence of disease and general debility is nearly 100 per cent in those with a poorly developed thorax.

The question now is: Can the debility be the result of the poor development or is the poor development the effect of disease conditions? Looking at it from a purely inductive standpoint, we see that there are just as many—thirty-eight—persons undernourished and defective who have normal thoraces as with subnormal chests. It is logical to conclude then that as we find debility more frequently associated with a normally developed chest than with a subnormal and yet the incidence of disease or debility is ten times greater in the under-developed thorax, therefore the lack of chest development is the cause rather than the effect.

Thoracic Movements and Circulation

A comparison of a fairly large group of persons with under-developed thoraces in persons having normal fully developed thoraces has shown that such a deficiency has a marked influence on general bodily vigor and the state of nutrition, and accompanies a decreased resistance to disease. Just as common experience has shown that persons with flat or small chests are more susceptible to tuberculosis, we have observed in this series a similar weakness in respect to other diseases. The obvious explanation of this, and the one most likely to be advanced, is that the smaller capacity of the lungs decreases the oxygenation of the blood and does not permit an active metabolism. A little reflection, however, indicates that the rôle that the respiratory movements play in the gaseous exchange of the blood with the outer air is of secondary importance as compared to their effect on the circulation of the blood. To begin with, we know that the ordinary respiratory capacity of the lungs is far in excess of any ordinary need. It has been shown, for example, that the carbon dioxide in the inhaled atmosphere may be increased more than twice the usual amount without producing any discomfort. In all clinical conditions in which we find an interference with the respiratory function of the lungs, such as in pneumonia, there is generally a compensating increase in the respiratory rate; yet in these individuals with poorly developed chests the respiratory rate is not increased. The small chested type, under exertion, shows signs of fatigue long before any cyanosis appears. Cyanosis occurs far more frequently and more readily in pathological conditions affecting the pulmonary circulation than in those affecting the respiratory function, as in pneumothorax, pleurisy with

effusion, and advanced tuberculosis. The benefit obtained by this class of people by changing them to an outdoor environment has commonly been attributed to the influence of the purer air rather than to the stimulating effect of sunlight and changed mode of living, but we have never heard of anyone with sufficient confidence in this supposition to propose treating tuberculous cases in an indoor atmosphere, washed and properly oxygenated. As a matter of fact, the difference in percentage of oxygen in country air and thickly populated streets is so small a fraction as to be negligible. Men working in a very smoky atmosphere show conditions of health comparing fairly well with that of farmers. Common experience, therefore, leads us to assume that we have been endowed with a respiratory equipment far in excess of any ordinary demands that may be placed upon it.

While we could enumerate many other clinical conditions which might lead us to suspect that the aëration of the blood is accomplished in an easy and an ample way by the respiratory movements in even a poorly developed thorax, such reasoning by analogy is open to fallacy and at best can only be suggestive. There is plenty of evidence, however, that the continual changes of intrathoracic pressure produced by the rhythmic contraction of the diaphragm have a most profound effect on the circulation of the blood. A word regarding the mechanics of respiration may not be out of place here. The expression "chest expansion" has been responsible for much popular misconception as to the manner in which inflation of the lungs is brought about. The ribs themselves do not expand, as any anatomist knows, and yet a great many of them go on speaking and thinking just as if such an effect actually occurs. Through the action of the muscles of respiration a change in the shape of the thorax occurs so that the horizontal diameter is enlarged at the expense of the longitudinal. At the same time that this occurs, a contraction of the diaphragm causes this membrane to move downward so that the pleural cavity is greatly enlarged at the expense of the abdominal. This produces an increase in the intra-abdominal pressure and, when such an increase is great enough, there occurs some bulging of the abdominal walls. This latter effect is often spoken of as abdominal or diaphragmatic breathing, in contradistinction to thoracic breathing, and yet common sense will tell us that so long as we know the chest wall is a comparatively inelastic bony structure, enlargement of the pleural cavity can take place only at the expense of the abdominal cavity.

What does occur in so-called thoracic breathing is that the ribs are drawn forcibly upward by a rotation on their long axis and at the same time a sharp contraction of the abdominal muscles takes place, forcing the abdominal contents against the diaphragm and increasing the tension on that organ, thereby still further enlarging the pleural cavity. The expansion of the abdomen is upward and laterally instead of downward and forward, as in what is termed deep breathing. The fact that this type of breathing is found more common in women is in most cases due to the old fashioned practice of tight lacing.

It may be assuming too much indulgence to review these simple, well known facts of physiology, but they are constantly ignored to such a degree that we are justified in emphasizing them. How often is the fact that ease of respiration depends largely on intra-abdominal pressure recognized in the sick-room? How many thousands of hospital patients in whom the conservation of strength is vital to their recovery are lying prone on their backs without so much as a bolster under the knees to relieve them? How many school children are daily

forced to "sit up straight" in stiff, unnatural postures because they may get round shouldered when they instinctively know that a humped up position is far more comfortable? If my teachers didn't want me to slide down on my back bone, why didn't they put in seats instead of perches to balance on? The place to stiffen a child's back bone is on the playground, not by making him miserable on awkward, right angle seats as if his back bone were meant to be a concrete pillar hinged on his legs. Comfortable seats when they are studying is essential for children. You sit more comfortably in a chair tilted back against the wall because it relaxes the abdomen, and makes it easier to breathe. Women can not appreciate that because they wear high corsets. They are always out of breath. Why does a tired man draw his knees up when he lies down to sleep? Formerly I wondered why dyspneic cardiac cases often prefer to lie on their sides rather than be propped up. I understand now. They had to push against a tight belly every time they took a breath. When a woman faints, her corset must be loosened but you never asked why except that you knew it made it easier for her to breathe. Not all physiology is learned in the laboratory.

The chief point in all this is the decided effect that this alternating rise and fall of pressure in the pleural and abdominal cavities has on the flow of blood from the portal system into the intra-thoracic veins. The capacity of the portal system is nearly as great as all the rest of the veins in the body combined. Picture, then, the flow of blood that must take place when pressure is applied to this great lake simultaneously with a release of pressure or suction produced within the thorax by the act of inspiration. This same suction has its effect on the flow of blood from the veins of the head and upper trunk into the superior vena cava, although the effect is not so marked in the upright position on account of the constant action of gravity. The effect of this movement of blood toward the heart must make itself felt all the way back to the peripheral capillaries resulting in a decrease in the resistance to the flow of blood from the arterial into the venous system. As there can be but very little back flow of blood on account of the valves in the peripheral veins, the increased volume of blood in the venae cavae must escape into the heart when expiration causes a rise in intra-thoracic pressure. This causes the heart to fill more rapidly and fully during diastole, with a consequent increase in the rate and force of the heart beat.² The dilatation of the heart sometimes produced by taking several rapid deep inspirations may be sufficient to cause a transient giddiness and roaring in the ears.

The powerful part that the respiration plays in the circulation of the blood may be readily observed in most any blood pressure tracing and becomes more noticeable in conditions that produce a fall in the arterial pressure. Recently Sewall² in a most delightful presentation of this subject has shown that by following the method of applying auscultation in connection with the pneumatic cuff used by Foiey, Coblentz, and Snyder, this influence of respiration on blood pressure changes may be readily demonstrated in a clinical way. Using this method, he found a decided difference in the systolic pressure during inspiration and expiration varying with the depth of respiration from 5 to 40 mm. A difference of 40 mm. means that with a normal pulse pressure of 40 mm., we may by taking deep inspirations and expiring forcefully add to the systolic force of the heart beat by 100 per cent.

It is to be remembered that along with this measurable increase in arterial pressure there is produced a decrease in the resistance to the venous return, so that there should be a still further increase in the velocity of the blood flow beyond that resulting from the increase in systolic force.

It is very easy for one to demonstrate to himself this relationship of respiration to the output of the heart. Let him try to make even the smallest kind of forceful muscular exertion, such as tightly clenching the fist, and he will find that he involuntarily adds to the force or depth of his respiration. When such muscular exertion becomes violent enough, as, for example, in heavy lifting, the expiratory effort may be made with such force as to cause a grunt to accompany it. Anyone's observation will verify that.

This discussion would scarcely be complete without a few remarks on the most desirable method of developing the thorax. While it may be perceived that any sort of athletic exertion will have its effect in promoting the vigor and depth of the respiratory excursion, such activity naturally will not have nearly so pronounced a result in building up the muscles of the thorax as will those movements which call directly into action the accessory muscles of respiration. Furthermore, there are several muscles attached to the ribs which take no part in respiration but, in fact, exert a counter force. These are the *serratus magnus* and the abdominal muscles. Nevertheless, any development of these must stimulate a greater growth in their bony support. By adding to the resistance to the action of the respiratory muscles they compel them to work harder and so there is a compensating hypertrophy of the latter. Common observation will bear this out. As a class the farmer lad or the young factory hand, persons who are obliged to do a great deal of heavy lifting, swinging an axe, etc., have larger and stronger frames than the athletic high school or college youth. The latter may be just as active and perhaps consume more energy than the former class, but their movements are of a light, quick nature rather than prolonged steady strains of the trunk muscles.

The sort of athletic games and exercises practised in our gymnasiums are not calculated to develop a robust, sturdy type. They cultivate beautiful muscle coordination and dexterity and agility, but poor staying power. Such exercises as do call into play the trunk muscles to a large degree, notably swimming, are so violent that they can not be long sustained. Persons desiring to develop the shoulder and trunk muscles and indirectly enlarge their chest measurements, should work with the saw-buck, the axe, the pick, and shovel, the scrub brush, and the sledge. If something more genteel and less remindful of irksome labor is demanded, then we can substitute the medicine ball, putting the shot, and the setting up exercises carried out with a heavy rifle as taught in the manual of arms. The fault with so many physical culture systems is that they undertake to accomplish in fifteen or twenty minutes what should be spread over two or three hours at least. We hear a great deal about military training as a means for attaining physical efficiency, but we lose sight of the fact that a little industrial training might also have considerable merit in that respect. In our opinion, many men are forced into the lighter occupations for which they are unfitted simply because in their youth and school days they neglected the kind of work that would have given them the robust proportions and vigor necessary for the heavy labor in the industrial arts. Also, it is possible that we have here the explanation of why the men who grow up on the farm rise to such eminence in city

2. Sewall, H.: On the Clinical Significance of Postural Changes in the Blood Pressures, and the Secondary Waves of Arterial Blood Pressure. *Am. Jour. Med. Sc.*, 1920, clviii, 786.

life in spite of the handicap of a district school education and other disadvantages in mental culture. It is simply that they are able to out-work the other man.

Health Through Hard Work

Absolutely nothing was found in this investigation to bear out the notion that variations in the length of the abdomen as measured from pubis to sternum have anything to do with constitutional inferiority.

It was found that variation in the length of the long bones occurred with much more frequency than variation in the length of the trunk. A long trunk is sometimes found associated with short legs but not nearly so often as a short body is seen in connection with long extremities.

Next to the body weight, the chest measurement may be said to be the most important index as to general efficiency. The body weight, taken into consideration along with the size of the chest, affords a fairly accurate index of the general health of the individual, and of that person's capacity for hard work.

The average chest measurement in 309 examinations was 34.63 inches.

All those whose chest measurements were an inch and one-half or more below the average showed decided evidence of physical impairment and general debility.

This close relationship of the size and strength of the thorax to general well being is explained by the effect that the respiratory movements have on the circulation of the blood.

In this connection it is pointed out that, contrary to a prevalent erroneous conception, the abdominal muscles do not assist in inspiration but rather oppose it; and, for this reason, the most restful sitting or reclining posture is one which permits abdominal relaxation. Proprietors of theaters and other places furnishing amusement to the tired business man should bear this in mind and fashion their seats accordingly.

A great part of the study of the circulation in recent years has centered about functional activity of the heart. Some notable contributions have been made to medical science, particularly in respect to the mechanism controlling cardiac rhythm and its disorders, as well as newer methods in testing the functional capacity of the heart muscle. Through the interest aroused in these discoveries, however, we have come to focus our attention too much on the heart as if that were the only element upon which circulatory efficiency depends. While the heart is the most contractile part of the circulatory system, it must not be forgotten that the blood does not flow through a rigid system of tubes, but in every part of the arterial-venous system there is continually taking place a change in pressure from sources either outside the vessel wall or in the contractile tissue of the vessels themselves. The influence of respiration on the circulation of blood is only one of the many factors that must engage our consideration before we can decide whether this or that person has a healthy circulation. When we consider that in the present state of our knowledge the treatment of many acute diseases lies largely in supportive measures, it may be conceded that a knowledge and understanding of every element that will maintain the circulation at its highest vigor with the least effort is highly desirable.

It is superficial thinking to attribute the delicacy of the modern woman, in such cases as its exists, to corsets, high heels, city life, etc., when the real truth of the matter is that it may be invariably traced to a freedom from the kind of work that develops big shoulders and strong backs. Physical development comes only through hard work.

"resistance exercises," if you prefer. To expect to attain such development with a few minutes daily spent at some light calisthenic exercises is like trying to move a mountain with a crowbar, you can only move a little at a time

INTERNATIONAL JOURNAL OF PUBLIC HEALTH

The November issue of the *International Journal of Public Health* contains an article by Leon Bernard on the war and social prophylaxis of tuberculosis, with the conclusion that out of our recognition of the duty of looking after the tuberculous soldier has developed the basis of a complete anti-tuberculosis organization. In order to attack tuberculosis at its source it will be necessary to include hygiene in the education of children and energetically campaign against alcoholism and radical changes in his conditions.

Dr. Alfred F. Hess reports the instance of scurvy during the World War, which was rather extensive, notwithstanding the fact that the condition is fairly simple of control. Very few cases are described on the western front, but it was most frequent in Russia and next in frequency among the nations neighboring Russia. There are many accounts of scurvy among Italian troops. The greatest amount of scurvy affecting civilian populations is reported from Austria, particularly in Vienna, and in Great Britain it manifested itself in institutions caring for the poor. We must still regard war and scurvy as associated evils, for war is closely linked with famine and food deprivation.

Other articles in the same issue are as follows: Leonard Rogers, "Leper Colonies and Improved Treatment in the Control of the Disease"; George C. Shattuck, "Treatment of Typhus Fever"; Massimo Sella, "The Antimalaria Campaign at Fiumicino (Rome), with Epidemiological and Biological Notes."

DR. SAMUEL J. MELTZER DIES

Dr. Samuel J. Meltzer, of the Rockefeller Institute for Medical Research, who contributed many important discoveries to medical science, notably the method of "pharyngeal insufflation," died in New York, November 7, 1920. He was born in Russia sixty-nine years ago, received his general education in Königsberg, Prussia, and then studied philosophy and medicine at the University of Berlin.

In 1911 Dr. Meltzer announced the scientific proof of what he termed a "peripheral mechanism" for distributing substances throughout the body aside from the circulatory system of the heart, veins, and lymphatics. As a result of the special studies of wounded soldiers made at the institute in 1914, Dr. Meltzer discovered a new method of treating lockjaw. His device previously used in artificial respiration was found available against tetanus.

Dr. Meltzer held the rank of Major in the Medical Officers' Reserve Corps. He was a member of many medical societies and had been president of several, including the Association of American Physicians. He wrote more than two hundred monographs on biology, physiology, and allied topics.

UNREST LAID TO NERVES

The State Conservation Commission of New York in a recent report urges as an offset to the social unrest attributable to the requirements of modern efficiency that education be given to the conservation of wild places and wild life to promote the general physical and mental well being and happiness of the people.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing,
Maternity Care, Child WelfareKATHERINE M. OLMSTED, R. N., *Editor*

FACING THE FACTS

WE NOTICED in the November issue of *Hospital Progress*, official magazine of the Catholic Hospital Association of the United States and Canada, a very well written article on the "Shortage of Nurses," by Dr. Edmond G. Zimmerer of Lincoln, Neb. We agree with Dr. Zimmerer when he asserts that "there is just as much reason for lowering the educational standards of schools for nurses in the present emergency as there would be in closing colleges and universities in order to fill the depleted ranks of the harvest hands or railroad laborers. The slightly educated nurses are always the first ones by legal or illegal means to raise the fees, which makes it just as difficult for the poor man to secure the services of even a poorly qualified nurse."

Our poor people and our laboring classes will never be properly nursed in their homes at times of illness until we have—not "poor nurses for poor people"—but good, intelligent, well trained nurses, supported by public funds, who will give bedside nursing when needed, and who will be called upon by all people in time of need, as they now call upon the public servants known as police, firemen, and health department experts.

Dr. Zimmerer spoils a good argument, however, by saying that "the talk of shortening the course for nurses and reducing somewhat the preliminary educational requirements has met with some protest, it is true, but mainly this protest comes from those who are selfishly interested in seeing that the field is not too crowded"; however, he does express the hope that their protest will not be heeded.

We regret very much to hear that Dr. Zimmerer has among his acquaintance some nurses who may belong to the opposition and favor lowering the standards of our schools; but we wish to assure him, and the possible readers of his article, that nurses, as individuals and as groups, everywhere stand for higher requirements and better training.

The state nursing associations both in Missouri and Iowa have at recent meetings unanimously voted in favor of raising the requirements of schools desiring to be accredited by state legislation to four years high school entrance requirements, and undoubtedly many other states are doing likewise.

The lay people, directors of the hospital, and training school boards are everywhere beginning to recognize the significance of the evident reluctance of young women to enter this profession, and that its cause has not necessarily anything to do with the caliber of the young women of today. It has, though, something very seriously to do with the status of nursing as a profession, and, also, with the opportunities for training which are offered.

If the body of men and women who are now in control of schools for nurses take the task seriously they might do much in finding a solution of the present situation by conducting an independent research into the situations which exist in their schools for nurses.

Anyone who has had anything to do with sickness, in private homes or in public health, knows that the shortage of nurses is no imaginary one and that within the last year a decidedly decreased number of students have entered schools for nurses, the single exception being in those schools which have notably high educational standards.

The focusing of the public interest upon nursing problems has been quite disconcerting. The veil of sentimentality vanishes and much appears as it really is. A group of community servants entirely well intentioned, but more or less poorly prepared for their tasks, are being placed in an urgent field. The recent inquiry conducted by the Rockefeller Foundation regarding nursing and the education of nurses will entail some extraordinary revelations, undoubtedly demonstrating the fact that present policy in nursing education is discredited by its results and that a sane, sound, reasonable plan needs to be put into operation under able leadership at once.

Present conditions in nursing education may be summed up as follows: Any person or group of persons may assemble a number of sick persons under a roof and call the place a hospital and they may start a school for nurses, offering young women instruction in one of the most vital and difficult arts. It is not necessary to assure competent educational authorities that the school can provide proper instruction, or even suitable living and working conditions. The fact that many hospitals do their best to keep faith with their pupils does not lessen the need of a competent authority which guarantees that pupils entering schools for nurses will receive sound and systematic instruction in their chosen calling. Attempts are being made in the various states by the graduate nurses' associations to formulate certain standards and to conduct inspection, but inspectors, to be useful, must carry certain authority.

Various panaceas have been recommended to relieve the situation, such as shortening the course, lowering educational entrance requirements, and increasing the monthly allowance—none of which will in any degree lessen or alleviate the critical condition in which the profession of nursing now finds itself. Proof of this is evident in the fact that the only schools for nurses in this country which are not suffering from a shortage of students are the ones which have held their standards high above all that laws demand, the schools which keep barely up to the level of the requirements of the laws in each state are the

ones which are suffering most severely from the shortage of pupil nurses. That many prominent persons are becoming keenly concerned about the nursing situation is evidenced by the following letters recently received.

Dr. Irving Fisher, of the Department of Political Economy, Yale University, affirms that "changes should be made as following in most existing schools for nurses: Use the eight hour shift. It is a wonder that nurses in their hospital training have so long stood the long hours of work and perpetual strain. . . .

Have ward workers to do the cleaning work and even make beds in rush time.

Nurses should have a whole month's vacation in each year of training, in order to keep their health unimpaired."

The psychological effect of the "all powerful" supervisor is something terrifying to the younger nurses. It seems to me very important that the salaries of supervisors should be raised so that the very best women can be obtained. Supervisors ought to have teaching ability and should be big enough women to know thoroughly the points of view of the younger women and how to "get at them." In other words, supervision should build constructively instead of destructively.

In remedying the present shortage of nurses, the hospitals should not lower their standards, but raise them.

Dr. Livingston Farrand, director of American Red Cross, says:

There is no one problem in the present health situation in the United States more important than that of increasing the number of nurses and assuring the quality of those who enter that profession.

If there is one fact that has been developed in the public health campaigns of the last two decades, it has been that the nurse is the central factor in applying practically what we want scientifically as to the prevention of disease and the building up of community health. The shortage in nurses following the war has created a critical condition and one that must be met if progress is to be made. I feel, therefore, that the concentration of effort along this line is called for from every agency in the country.

Dr. H. S. Cumming, Surgeon General of United States Public Health Service, recently stated that:

The time has passed when the establishment of training schools for nurses can be looked upon only as a means of having the nursing in hospitals done for a minimum cost, and if the hospitals are to keep up their quota of pupils and sufficient nurses trained to meet the country's needs, some radical changes in the attitude of hospital authorities toward pupil nurses are necessary.

It is a well known statistical fact that nurses, in their service, pay a higher tuition fee for their education than is paid by any other students in the world, therefore, among the changes considered necessary should be:

(1) Proper instruction in nursing education with paid, qualified, part time or full time instruction; recognition by boards of directors of hospitals conducting training schools, that the nurses' training school is an educational institution, and the service she renders is full payment for an adequate education.

(2) Sufficient time off duty for study, rest, and recreation.

(3) Affiliation with other schools of nursing and nursing organizations, such as public in its various forms, social service work, etc.

(4) Training schools for nurses should be registered if pupils are accepted.

If well bred, well educated, intelligent women are to enter the profession of nursing—the kind of women urgently needed—hospital authorities must recognize the necessity for making living conditions bearable, hours of duty shorter, and possibilities for nursing education greater.

Prof. C.-E. A. Winslow, School of Medicine, Yale University, asserted:

We are on threshold of an epoch-making period in nursing education. It is recognized by all thoughtful students

on this subject that the number of student nurses can be increased, not by lowering the standards and making the pathway easy, but by improving the character of the education offered; and the training school of the future will be an institution of university grade, capable of attracting and holding the best type of young women in the country.

There are no natural qualifications and there is no type of preparation too good to equip women for the demands of the nursing profession of the present day. I believe that there is no other career that promises so much usefulness, so much satisfaction and so large a field of service to a woman as does a career in nursing, with the tremendous opportunities for institutional management and for the direction of public health activities which the tendency of events is creating.

The interest and cooperation of people like the above in the struggle being made by nurses to not only maintain, but raise nursing standards, makes us all take courage. We realize an occupation is not a profession simply by calling it one. But today the education of the nurse is undergoing such close scrutiny and so many readjustments are being made that it is fast becoming scientific, and soon the combination of a scientific education and a most useful calling will make it unnecessary for us constantly to have to enunciate the fact that "nursing is a profession."

NATIONAL AID FOR MATERNITY

THE proximate passage of the Sheppard-Towner Bill¹ is the object of a nation-wide interest which is being manifested by the child welfare committees of all national and state associations interested in promoting better health conditions. This bill has for its object the public protection of maternity and infancy. It provides for instruction in the hygiene of maternity and infancy and the household arts essential to the well being of mother and child; it provides for consultation centers and medical and nursing care for mothers and infants, at home or at a hospital.

It is recommended that the act be administered by a Federal Board on which are represented the United States Bureau of Education and the United States Public Health Service. The executive officer of the Board is the Chief of the Children's Bureau.

In the separate states the act may be administered by the Child Hygiene Division of the state board of health or, where such a board is lacking, by a specially created state board.

To carry on the provisions of the act, the Federal Government is to appropriate \$2,000,000 the first year, this sum to be annually increased until it reaches \$4,000,000.

It will be apportioned among the states in the proportion which their population bears to the total population of the United States, provided that each state appropriates a like sum. In addition to this sum, the bill provides for an annual appropriation of \$480,000 to be divided equally among the states without guarantee of a like sum.

It should be noted that the separate states are free to carry out their approved plans without interference from the Federal Board; that the Federal Government in this act does not propose to embark on a medical or

1. Since this editorial was written the Sheppard-Towner bill passed the Senate after opponents of the measure forced material modifications from its original form. As approved by the Senate the bill does not provide for more than a campaign of instruction for the expectant mother and for the care of infants, the provision for medical and nursing attention having been stricken from the bill. Instead of creating a new bureau for carrying out the purposes of the act, the Children's Bureau is directed to administer the act, and the expenditure as originally proposed of about four million dollars was reduced by about \$1,500,000 a year.

surgical campaign, but rather to stimulate and guide and make accessible instruction and care to all mothers and infants; that this service is in no way compulsory.

The Children's Bureau has shown by its investigations of the past seven years that the United States is wasting the lives of mothers and babies. It has recently been quoted that "a survey in rural areas in six states, as carried out by the Children's Bureau, shows that 80 per cent of the mothers had received no advice or trained care during pregnancy, due often to the inaccessibility and lack of hospitals, doctors, and nurses. It shows practically no organized effort to meet the need for instruction in prenatal and infant hygiene and for trained care during the period of confinement. The cost in many cases for providing adequate care was prohibitive.

"Of more than 22,000 city babies studied by the Children's Bureau, representing every type of home in seven cities, more than three-fifths were born into families where the father's earnings were below the amount which was at that time the minimum for providing the bare necessities of existence. Only one in ten was in a family where the father's earnings reached a fair minimum for comfort. Without the aid provided by the Sheppard-Towner Bill they are in no position effectively to safeguard their children."

Public health nurses are everywhere keenly interested and desirous of the immediate passage of this maternity and infancy bill. Every nurse should mention it and

explain it at every meeting she attends in city, small town, or rural district; and should see that in her town plenty of publicity is given to it in papers and at meetings.

LEAGUE FOR THE HARD OF HEARING

Public health nurses will be interested in the fact that the hard of hearing in Chicago have organized a league for mutual aid and improvement and to give vocational education to soldiers who were affected by deafness in the service. The league is officered by prominent men and women of Chicago who have given it their endorsement. Its headquarters are in the Auditorium Building in Chicago, its work being divided as follows:

Educational: Four free practice classes per week in lip reading. Additional practice can be obtained through league officers. It acts as a clearing house and reference bureau on all subjects pertaining to hearing.

Recreational: The League offers a large meeting place for social gathering. A tea and social hour are on the Saturday program. Lectures and special programs are given once a month. Card clubs meet twice a month. The men's club meets on Saturday evenings and the young people's club on the first Wednesday of each month.

The League has been designated by the Federal Board for Vocational Training to furnish lip reading instruction to deafened soldiers and sailors of the late war.

THE PUBLIC HEALTH NURSE IS A TEACHER

SO many nurses are now giving classes in the "care of the sick" in schools to high school girls, in factories to working girls, and in clubs and homes to groups of mothers and young women, that the following suggestions will be most helpful. These have been compiled by the Red Cross in an effort to help the instructors of the classes in home hygiene and have been found most interesting.

For Nurses Who Teach

1. Warn people of the necessary care should an epidemic appear.

HEAT

When heat is wanted, resort may be had to the electric grill, the alcohol flame, or to the "canned" variety.

2. Try always to make lessons practical, employing the things which will prove of value in the future.
3. Demonstrate carefully and explicitly, seeing that each student with her own hands succeeds in following your directions.
4. Teach prevention of unnecessary disease and the preservation of health. To common sense add technical knowledge.
5. This home nursing work is national service as well as a home duty.
6. In demonstrating plasters, poultices, etc., make small samples so as to conserve material.

7. In each case, after arrival in the field arrange for someone to make under your supervision and direction a bed cradle head rest, and stupe wringer.
8. In small communities you will have to carry some of your equipment from one teaching center to another, thus avoiding asking the people to secure things which are difficult for them to get in their community.
9. Emphasize that this instruction is for home nursing only.
10. Tell the people that one-third of our young American manhood was found unfit physically at the time of drafting; that 16,000 women die in the United States

SUBSTITUTES FOR HOT WATER BAGS

To the ingenious nurse a variety of substitutes for the hot water bag are available.

every year from child-birth; that 90 per cent of the sickness in the world is in the homes; that 5,000,000 people were victims of the influenza last year, and 400,000 of them casualties; that 300,000 infants die every year in the United States from preventable causes; 70,000 infants under two years of age die annually in the United States of diarrhea and enteritis; that it is the ambition of all women to see if we can reduce the mortality figure 100,000 this year.

11. Tell your students that one way of fighting the fly menace is by using 2 per cent solution of formaldehyde, which is twenty parts water to one of formal-

Cleated boards placed at one end of a dripping pan transform it into a satisfactory substitute for a bed pan.

dehyde, in a saucer. This can be sweetened a little or dropped on a small piece of milk soaked bread. This is effective if all other fluids are put out of reach of the flies. A fly deposits from 75 to 125 eggs each time, and it takes but ten to twelve days for full development; only eight to ten days more and they are ready to lay eggs.

12. Be sure to tell the women the importance of isolating patients, using paper napkins and paper bags for excretions, care of fingers, and putting to bed in case of infectious colds or influenza.
13. Don't fumigate.
14. Don't wash the baby's mouth.

Colon tube attached to teapot or paper funnel for enema

An ordinary teapot or a paper funnel may be employed in giving an enema.

15. Emphasize at all times the importance of early detection of communicable diseases, *e. g.*, diphtheria, etc. Illustrate by examples in which patients suffering from diphtheria were treated for ordinary "sore throat."
16. Teach people to keep a child with cough and nasal discharge away from other members of family and by all means out of school.
17. Continually emphasize the remedial and disinfecting

properties of air, and sunlight. Encourage rural people to admit sunlight into every room in the house *daily*, especially when there is an infectious disease in the house.

The simple device of using a covered swing board saves a patient the discomfort of sliding in bed.

18. Always teach them to give plenty of water to patients suffering from any communicable disease.
19. For communicable diseases select the sunniest room in the house and always ventilate summer and winter.
20. Explain futility and absurdity of such measures as: the use of camphor, asafetida, sliced onions, plates, of chlorid of lime, carrying burning sulphur through

A clothesline, or a strip of sheeting, tied to the foot of the bed, will aid the patient in raising or turning herself.

room, etc., as disinfectants; also pinning towels in front of open windows, tacking sheet in front of doorway to prevent the transmission of infection.

21. Explain and repeat necessity of boiling clothes, dishes, and all material coming in contact with a patient suffering from communicable disease.
22. Encourage discussions and the asking of questions.
23. Never become technical. Bear in mind difference between teaching nurses and teaching groups in home care of the sick.
24. Show concretely how to prepare a room in a home in which a patient suffering from a communicable disease will be nursed.

To relieve the patient from the weight of bedclothing, place a board or a leaf of table across the foot of bed.

Tests of our Teaching

1. Do we always speak the language of the groups we are teaching?
2. Do we test the material presented to our groups

An ordinary rocker, with two pairs of roller skates, provides the invalid with a wheel chair.

before ascertaining whether or not we have considered the plane of their knowledge?

3. Do we convey tangible facts, and can a practical application be made in the home of every point we teach?
4. Do we teach up to the limit of our knowledge, or do

A blanket and an umbrella constitute an "inhalation tent" that answers every requirement.

we invigorate and enrich our lives by the acquisition of new knowledge and information pertaining to our problems?

5. Is our teaching mechanical, or perfunctory? Illustrate.
6. Is our method of presentation always clear, related, methodical, or is it a bunch of unrelated material?
7. Is the lesson always adapted to age, type and mentality of our groups?

How to Improve Equipment

Inhalation outfit.—Place steaming tea kettle in pan of coals on chair. Make tent for patient with blankets and papers hung over cord attached to head of bed, patient and steam to be inclosed in open umbrella covered with blanket.

Place pillow-covered rocks or sandbag under knees

To prevent a patient from slipping in bed, place pillow-covered rocks or sandbag under knees, or place under the knees a pillow-covered broomstick tied to the head of bed.

Substitutes for lubricating enema points.—Face cream, sweet cream, salad oil, unsalted lard and lard substitutes.

To elevate bed.—Remove castors and place legs of bed on blocks. Place blocks or substitutes beneath corners of springs.

Back rests.—Suit case held in place by bandage, inverted chair, or bread board braced with sand bags or tied with bandage, makes a satisfactory back rest.

Bed table.—Ironing board resting on chairs which are placed on opposite sides of bed, a bread board supported on books, a soap or cracker box with three sides removed, or a home made table with short legs can be used for a bed table.

Protecting patient from draft.—Pin blankets over clothes horse or a blanket over rope stretched from head to foot of bed to protect the patient from a draft.

Prevent patient from slipping in bed.—Place under knees pillow folded over broomstick, then a broomstick tied to head of bed.

Exercising baby.—Low pen may be made from packing box, or by stretching chicken wire around post driven in ground.

Steam or hot pack.—Take dry corn cobs, put into water and let come to boil. Protect patient with blankets and newspapers. Place cobs on top of lower blankets and cover closely with another blanket.

Patient's tray.—Dripping pan—cover with napkin.

Graduate for measuring any liquid.—Quart jar with strip of adhesive side of jar, the ounces being indicated on adhesive.

To relieve pressure under back, elbows, heels, or hips.—Stitch together two circular pieces of cloth of desired size leaving small opening on outer seam. Fill with cotton,

This improvised bed table is made with an ironing board which rests on chairs.

hair, excelsior, or bran and sew up opening.

Bed pan.—A cleated board may be placed over one end of dripping pan to be used as an improvised bed pan; or, use a shallow washpan, the patient's hips to be raised slightly and supported by nurse's hands or a pillow.

Enema can.—The colon tube may be attached to a paper funnel or a teapot.

Prevent a backrest from sliding by bracing it with rocks or sandbags.

To cool fever patient.—Fill bottles or rubber hot water bags with cold water. Place bottles or bags under patient's hands at back of neck or on forehead. Keep water cool.

Hot water bag.—For application of heat to abdomen, use hot flannel, aluminum pie tins, or kettle covers covered with a towel. For limbs, fruit jars, jugs or bottles filled with hot water and covered may be employed with precautions against leaking or burning.

Bed cradle.—The best cradle is made from barrel hoops nailed together with lath and cut to fit the patient. Use pillows at each side of limbs or abdomen to remove the

weight of the covering in some cases. A light weight folding chair can be placed upside down under covering to good advantage. Sometimes a camp stool can be used.

Headrest.—For this purpose use a brace nailed to a

A suitcase held in place by a bandage will serve as a backrest.

large board or a dining chair, placed upside down with top of chair back toward lower part of patient's spine, with pillows between chair and patient's back for comfort.

High bed.—Ordinary bed should be raised by use of blocks.

Bed protection.—Substitute for oil sheeting, newspapers, cheese cloth pads, clean worn out quilts or blankets cut into pads the desired size.

Urinals.—Use tin cans or milk bottles which can be destroyed when no longer needed by patient.

Feeding tubes.—Use straws or flaring tumblers filled half full to allow gradual tipping without spilling.

Iceless coolers.—Vessel of aluminum or crockery may be kept refreshed by refilling with cold water, the top to be covered with cloth wrung out of cold water. Food placed in this cooler keeps fresh for some time.

Screen.—Strong cord or wire may be stretched across room two or three ways, over which to fasten sheets so that they will slide easily aside when not needed.

Sick room door.—In hot weather use one square of muslin, sew loops or rings in each of the four corners, fasten to hooks in door casing, hang top edge just above level of eyes when standing.

Chamber for infant.—Cut round hole in bottom of ordinary child's chair, place under chair a vessel that could be used for that purpose alone.

An inverted chair will serve to elevate the head of the patient.

Bed table.—For bed table a twenty-seven-inch board with nine-inch legs at each corner or boards nailed at each end for support when it is used across a bed patient's lap.

My general philosophy of education is that its broad and ultimate function is to extend the area of human happiness and to promote the general welfare of humanity.—James H. Harris.

INFANT WELFARE WORK IN LOWELL

By KATE KOHLSAAT, R.N., SUPERINTENDENT OF NURSES, LOWELL, MASS.

LOWELL, Mass., as probably everyone knows, comes near the top of the list, sometimes achieving the very top in the matter of high infant death rate. On account of this the Lowell Guild Visiting Nurses Association has placed special effort in the past year on the extension of the work of its baby hygiene department.

The clinics for sick and well babies held in the Guild rooms, 17 Dutton Street, on Tuesday and Friday of each week, attained such proportions that it was deemed advisable, during the summer months at least, to establish branch clinics. With this thought in mind the Board of Education was approached and they generously gave the Guild the use of a room in two school buildings that

idea of the difficulties encountered may be imagined from the fact that seventeen nationalities are represented in the conferences of one month. Fully 50 per cent of the mothers attending conferences are French Canadians and Greeks, so we have found it most advantageous to have a nurse who speaks French fluently and is able to understand Greek fairly well. We have been fortunate in securing the services of a Greek social worker as interpreter when our problems become too difficult for the nurses to handle. The atmosphere of our conferences is splendid, the mothers are all joining in conversation and in admiration of one another's babies. The most discouraging feature of the work is the fact that the mothers are allowed to work in the mills during the greater part of their pregnancy and then return to work as soon after confinement as possible. However, the results of the past three months, July, August, and September, are very gratifying and the work should be far reaching and have a wider influence each year.

During July there were two baby hygiene nurses in the field and in August a third nurse was added. These nurses have had 700 babies directly under their supervision. There were forty-seven clinics held with an attendance of 1,337 babies. The nurses made 2,673 home visits to instruct the mothers how to carry out the doctor's orders.

In 1903, or when the city of Lowell was smaller than it is now, there were 267 infant deaths for July, August, and September. In 1920 there were 113 deaths of infants one year of age or under during July, August, and September, this being the lowest record for the past thirteen years.

Mothercraft Is Taught

The nurses have been enjoying their classes in "Mothercraft" among the young girls of foreign parentage, the object being to teach the children simple rules in personal hygiene together with the proper care of the baby. It is surprising to see with what interest they proceed from lesson to lesson, for the children learn easily and in many cases it is only through the children that we are able to reach the mother.

In addition to the baby hygiene department, the Lowell

It is a lucky baby who has so many trained supervisors directly interested in whether it eats right and grows as it should. The child supervision in Rochester is a boon to mothers, and a direct social asset.

could be used as clinic conference rooms during July and August. These school buildings, located in entirely different parts of the city, together with our location at 17 Dutton Street, equalized the distribution of our efforts fairly well over the entire city.

Babies Given Right Start

Doctor and nurses were in attendance at each conference. The babies were weighed and a careful record of their gain or loss, together with their entire condition was recorded. The nurses try to teach all the mothers the importance of regular feeding, proper clothing, and fresh air, and the danger of over feeding. We realize how hard it is for some mothers to pay attention to detail when they have many other things to do and the baby cries most of the time. Our object is the instructing of the mothers in carrying out the orders of the conference doctors and encouraging maternal nursing whenever possible, thereby giving the baby the right start in life.

As there is a large foreign population in Lowell, some

The mothers who bring their babies to the Baby Hygiene Clinic can tell their troubles in their own tongue. Young girls are trained in Mothercraft, and the lowest record of infant mortality in thirteen years was reached this year.

The clinics take care of sick and well babies. All factors are fostered in the effort to give the babies a right start in life.

Guild has a staff of eight graduate nurses in the field, giving bedside care in the homes. Our prenatal nursing has grown within the past year and our aim is to fill the gap between the prenatal nursing and aftercare to mothers and babies by providing nurses at the time of confinement.

A special piece of child welfare work, with a staff of three nurses, that the Red

Cross is financing, also has its headquarters in the Guild rooms. Their clinics for young babies are held in connection with the Guild's clinics, but a separate clinic for the children from two to six years is held on Monday afternoon of each week.

An instructor from the Harvard Infantile Paralysis Commission holds a weekly clinic in our rooms, where she gives treatments to the children under their care; also a medical gymnast has two clinics a week, giving treatments to patients suffering from obstetrical paralysis.

With these various activities carried on under the roof of the Lowell Guild, no one can be blind to the fact that the Lowell Guild Visiting Nurses Association is doing its bit towards the better health conditions of the city.

PENNSYLVANIA ESSAYS TO PREVENT DENTAL CARIES IN THE SCHOOL CHILD

By GEORGE K. STRODE, M.D., INTERNATIONAL HEALTH BOARD, NEW YORK CITY, FORMERLY CHIEF, DIVISION OF SCHOOL HEALTH, HARRISBURG, PA.

EVER since medical examination of school children became an integral part of our public school system, attention has been focused on the teeth. This has been but natural, since, irrespective of the location of a school or the social status of the pupils, no physical defect occurs with such frequency as dental caries.

dren primarily requires preventive measures, certain far seeing dentists and physicians have developed campaigns based on the simple principles of dental prophylaxis. Perhaps the best example of such an experimental campaign is to be found in Bridgeport, Conn., where under the able direction of Dr. A. C. Fones a prophylactic dental service was installed about six years ago. The success attending this piece of work has long since taken it out of the class of experiments and it now stands as a splendid demonstration of the practicability of dental prophylaxis.

Impressed with the sound principles on which school dental prophylaxis is based and the sane methods devised for applying these principles, the Department of Health determined to further such work in Pennsylvania.

At the outset we were convinced that there was urgent need of attacking the dental problem. We were familiar with the extent to which school children's teeth are carious and the effects of carious teeth, not only upon health but upon academic progress. We knew dental caries to be chiefly a disease of childhood and adolescence, and that the teeth, if kept sound until past twenty, are most likely to remain sound through life.

A dental ambulance was made the medium of carrying out the measures of dental prophylaxis, a dental unit consisting of a dentist and two nurses. Outlying districts were thus reached.

A School Health Problem

Effort to correct the condition has resulted in the establishment of dental clinics in large numbers throughout the United States. Many of these clinics have been in operation for ten years or more and, therefore, ample time has elapsed in which to judge of their effectiveness. Those in position to know assert that dental clinics have been of great service but are entirely inadequate for the work at hand. Their function has been to repair the damage incident to caries and not to prevent the development of caries. As a consequence, the solution of the problem of dental caries has not been greatly hastened by the dental clinic, *per se*.

Realizing that the dental problem among school chil-

If 93 per cent of the children have "unclean" teeth, 100 per cent of them can be interested in dental prophylaxis if the right appeal is made.

Our task was essentially a school health problem and it seemed to us that the state Department of Health not only should indorse dental prophylaxis but should actually demonstrate to the school authorities what it is and how it can be applied in the school.

Fortunately, a mobile dental ambulance was made available to the Department for a short period in the spring of 1920. A dental unit was formed consisting of a dentist and two dental hygienists.

So far as we know, prophylactic dental service had not been attempted in any of the schools of Pennsylvania before these demonstrations. Dental clinics, however, had become fairly common, so that there was a ready soil in many places for the implanting of the prophylactic idea.

Plan Procedure of Demonstration

From the school boards of certain cities permission was obtained to make a demonstration in the schools. The nature of the demonstration was explained as consisting of: (1) Actual cleaning and polishing of the children's teeth by dental hygienists, this to be done by hand, using steel scalers and orange wood sticks in hand polishers, all stains and accretions being removed, giving the teeth clear, smooth, highly polished surfaces. (2) A charted examination of every mouth. (3) Tooth brush drills and class room talks on dental hygiene. (4) Filling of small cavities by the dentist in charge.

It was explained that the school routine would be but slightly affected. The tooth brush drill and class room talks were planned to occupy about fifteen minutes a day, but aside from these nothing was to be done in the class room.

The cleaning and polishing of the children's teeth were done outside the class room in folding dental chairs which were set up in any vacant room having good light, or in the end of a hall.

The demonstrations were scheduled to occupy from ten days to two weeks and the work was confined to fourth grade pupils, as we felt that more striking results were obtainable in children of ten or twelve years.

By means of a demonstration we sought to show the school authorities that it is practicable to give every child in a school prophylactic treatment. We promised to obtain accurate data on which to estimate the length of time it would require to carry out such work in all the elementary grades and to give a working basis on which to determine the actual cost per pupil.

The cleaning and polishing of the children's teeth were done outside of the class room. The folding dental chairs could be set up in any vacant room having good light, or at the end of a hall.

Health depends on missionary work. Remedial defects of all kinds are 18 per cent more prevalent in Class 4 than in classes 1 and 2, which districts are not so remote as those in Class 4.

Soon after a demonstration was begun, the dentist in charge would arrange for talks before the Chamber of Commerce, Kiwanis Club, Rotary Club, women's clubs, and other similar organizations. An earnest effort was made to interest not only the school authorities but other leaders in the community, for such an innovation could scarcely be incorporated into the school system without popular support.

During a period of four months, twelve communities, varying in size from 12,000 to 150,000, were visited. As the findings in these several communities did not differ materially from one another, they have been combined and are presented in the following table:

	No.	Per cent
Number of pupils examined. All teeth were cleaned and polished by dental hygienists	644
Number that used tooth brush ineffectually	460	71.4
Number whose teeth were not clean.....	603	93.5
Number with carious teeth.....	622	96.5
Total number of cavities.....	3,933
Average number of cavities per mouth.....	6.3
Total number of cavities filled.....	1,083	27.5
Total number of teeth extracted.....	528
Average number of minutes devoted to each child by hygienist.....	40

From these figures we note that 71 per cent of the children either used a tooth brush at such irregular or infrequent intervals as to be valueless, or did not use one at all. And it is safe to say that the great majority of the 29 per cent who cleaned their teeth daily did not use efficient methods. Otherwise we are at a loss to explain the 93.5 per cent of children whose teeth were not clean.

The dictum "a clean tooth never decays" seems to find confirmation in these statistics, which show the close parallel between carious teeth (96.5 per cent) and unclean teeth (93.5 per cent).

Tooth brush drills and class room talks made practical a system of tooth cleanliness. The most striking results are obtained in children of ten or twelve years from implanting the prophylactic idea.

Dental caries is dependent for its development upon two primary factors, bacteria and food débris. The ever present bacteria break down the food particles by the processes of fermentation and putrefaction, with a consequent production of acids. These acids attack the enamel at a vulnerable point, especially in crevices where food has an opportunity of resting. When the enamel is disintegrated, the softer dentine readily yields and the cavity rapidly enlarges. This process of decay is influenced by the nature of the food particles—the sugars most readily ferment; by the irregularity of the teeth—food particles more readily lodge between irregular teeth and are removed with more difficulty; and by the natural resistance of the teeth to decay—thin and defective enamel, a resultant of malnutrition in the baby, diminishes the resistance to decay.

Dual Cause of Dental Caries

That the mouth cannot be kept sterile is obvious, but that it can be kept reasonably free of food débris is equally obvious. It is possible, therefore, to eliminate within practical limits one of the factors upon which dental caries is dependent. The elimination of this factor is the object of dental prophylaxis.

Proud of her teeth. It is possible to eliminate within practical limits one of the factors upon which dental caries is dependent.

The rather long and, to the lay mind, formidable term, "dental prophylaxis," means "tooth cleanliness." The dental hygienist's function in the school is not only to clean teeth mechanically but to give instruction in mouth cleanliness and develop habits which will eventuate in the pupil's ability to maintain mouth cleanliness.

The need for prophylaxis is eloquently argued by the exhibition of the 6.3 cavities per mouth which our examinations disclosed. Can this need be supplied at a cost which school boards will consider reasonable? It has been our experience that one dental hygienist can care for approximately seven children a day and, since it has been shown elsewhere that children's teeth usually require mechanical cleaning twice a year, it is obvious that the hygienist could care for about seven hundred children during a two hundred day school term. Dental hygienists may be secured for about the same cost as a good grade teacher, from one hundred to one hundred and twenty-five dollars a month, and the hygienist will care for about seventeen times as many pupils as the grade teacher.

Our demonstrations succeeded in proving to the communities visited that the mouths of school children present a problem which calls for prompt solution. That the boards of school directors were favorably impressed with the practicability of the methods used in our demonstrations was evidenced most concretely by the action of one school board which voted the sum of fifty-eight hundred dollars for dental prophylaxis during the school year of 1920-21.

The success of the first four months of our campaign has determined us to continue the work until dental prophylaxis becomes an integral part of every school health service in Pennsylvania.

NORMS IN WEIGHT OF CHILDREN

There having been much discussion regarding the various height and weight tables for children published by the different organizations and apparently some confusion and doubt having arisen in the minds of many teachers and health workers regarding the accuracy of the different tables, it has long been regarded as desirable for the principal organizations which were putting out tables to meet in conference and consider the possibility of adopting a uniform table which would be acceptable to all.

For this purpose a meeting was called in New York on December 3, 1920, by Dr. L. Emmett Holt, chairman of the Child Health Organization of America, to which the following organizations were invited: American Child Hygiene Association, Child Health Organization, Federal Bureau of Education, Federal Children's Bureau, McCormick Memorial Fund, Nutrition Clinics for Delicate Children, Public Health Service, and the School of Public Health, Yale University.

The conference was attended by Dr. Bird T. Baldwin, Dr. Taliaferro Clark, Dr. William R. P. Emerson, Dr. L. Emmett Holt, Mr. Ira V. Hiscock, Mr. Frank A. Manny, Dr. Anna R. Rude, Mr. Sydenstricker, Prof. Edward L. Thorndike, Mrs. Ira Crouch Wood, Dr. Thomas D. Wood, and Dr. Robert M. Woodbury. The various tables now in use were critically considered and it was found that there was substantial agreement in the figures used by all, the difference in the tables being chiefly a matter of presentation or statement.

Dr. Baldwin was appointed a committee to draft a table embodying the suggestions made, to be presented to the representatives of the organizations at a subsequent meeting to be held within the next few months, before its final adoption and publication.

TRAVELING PUBLICITY CAMPAIGNS

THE itinerant trader has always been a bearer of news, but we are now becoming familiar with a new kind of peddler, whose pack contains new ideas of useful information, not goods. He goes about the country representing departments of national and state government and private organizations. His trade is in the interest of better citizenship and health, not profits. The activities of these peddlers have been described in a book, issued by the Russel Sage Foundation, under the title "Traveling Publicity Campaigns" with a sub-title "Educational Tours of Railroad Trains and Motor Vehicles" by Mary Swain Routzahn.¹ The mode of traveling has progressed from wagons to trains and from trains to motor trucks. The wares are helps to better crops, better homes, better health. Accounts of some one hundred and thirty educational tours by train, auto trucks, motorcycles, trolley car, wagon, and even by house boat, are drawn upon in assembling this review of a comparatively new method of education and publicity.

Makes Unique Appeal

The primary reason for the use of the popular educational tours on wheels is the easiest on which it can be made to include the more remote rural districts in the itinerary of well equipped speakers and graphic presentations of health exhibits. Its unique appeal gets and holds the attention of a public which would not lend an eye or an ear to the more familiar channels of letters, newspapers, and posters. The train or truck campaign has the dynamic value of personal contact for direct appeal, and its wake is usually marked by better local organization and stimulated activities along health lines. For the rapid dissemination of information over wide areas it does not of course compare with a method which duplicates the material of an exhibit and sends it out to all points at once from the central office. The cost and scale of dif-

The Children's Bureau of the United States Department of Labor has provided a big gray automobile truck, known as the Child Welfare Special. It is believed by the department that the ground can be covered better by the Special than in any other way.

ferent enterprises of this character vary so widely that estimates of the cost cannot be given from one car project. The book includes information on all these matters as well as programs and the planning of itineraries.

Trains have been used in organization work for a number of years. Agricultural trains have carried models

and methods direct to farms. Industries have been stimulated by propaganda tours and, recently, the methods which proved for the success in promoting the fruit industry, dairy products, and pure seed promotion, have been used in Liberty Loans, food conservation, and child welfare. The Kansas Health Car "Warren" has been no small factor in the recent impetus given to child welfare

The New York health automobile carries motion picture apparatus, for both indoor and outdoor exhibits, as well as dispensary equipment for holding clinics.

organizations in Kansas. A test of the value has been made of the "Child Welfare Special" recently put into the field by the Children's Bureau. This car is roomy enough to provide a conference room and two drawing rooms. Most of the equipment is built in. Favorable report is made on the success of the "Special" in its hold on the public interest, and the physician in charge believes that the ground has been covered better by the "Special" than would have been possible in any other way. It has served well its most important function of stimulating local organization and in permitting follow-up work by the community.

The Healthmobile of New York is a large automobile truck especially designed to carry to the more isolated rural sections of the state the same procedures which have been effective in the centers of population. Besides laboratory equipment, it carries motion pictures and exhibit material, it transports speakers who hold health meetings and conduct child welfare demonstrations and examinations throughout an itinerary which covers systematically the more inaccessible parts of the state. By this means the Health Department is in a position to cooperate with any local committee which makes its wants known. Louisiana, also, has made extensive use of traveling health campaigns. A pioneer in carrying the message of health over the state in trains was Dr. Oscar Dowling, president of the Louisiana State Board of Health. The continuous tours of the Louisiana train have demonstrated its value. One car of the Louisiana Health train has been turned into a traveling publicity health laboratory, which enables the sanitary inspection of any town visited. This train has attracted the attention of health workers in other states and has made a number of trips outside of Louisiana in response to their request.

The two chief advantages of the educational tour as a

The health car of the Louisiana Department of Health. One end of the laboratory car is fitted up as a garage. Here a Ford is stored ready for use by the inspectors for a quick tour of each town visited.

publicity method are seen to be, (1) in bringing before scattered audiences—often in out-of-the-way rural districts—well equipped speakers and good graphic material otherwise prohibitively expensive; and (2) the news interest attendant upon the visit of the train to a town. This form of publicity cannot, of course, be well applied in campaigns which require the dissemination of information over large reaches of territory at practically the same time; but it is undoubtedly the quickest way of displaying the same objects to a number of communities.

MORE ABOUT THE COUNTY FAIR*

By STELLA FULLER, Extension Secretary, Central Branch Office, National Organization for Public Health Nursing, Chicago.

MANY magazine writers prepare their special season articles many months in advance. Vacation stories are difficult to write when snow and ice are on the ground. For the same reasons it is hard to write interesting fiction about winter holidays in July. Neither is it easy or wise for health workers to wait for early spring to plan work for next year's county fair.

Now is the time. The recent fairs are still in mind and nurses are discussing the results of their health programs. The health worker should have a notebook or, better still, a card file which would remind her of special duties to be carried out at different times during the year.

Get the People to Help

As early as April or May, when schools are still in session, a publicity campaign concerning the health work at the county fair should be well under way. With the co-operation of the county superintendents of schools, the nurse might send out two letters, one to the teachers and one to the children of the whole county.

In these letters she should outline in an interesting, friendly manner her plans for the autumn fair, giving a list of suggestions and asking each school to volunteer ideas for the program.

At the same time an article should be placed in the county papers informing parents and people in general concerning the plan, and, of course, the nurse should speak about it at all the schools she visits and whenever she addresses public meetings. The churches are always glad to cooperate. One western pastor was willing to put health notices in the church bulletin.

Sticker stamps or leaflets are good advertising and may be used to carry a health lesson as well. These could be included with parcels by local storekeepers during the month previous to the fair.

The nurse might carry in her car a silk banner or other prize to be shown to the children and later given to the school making the best showing at the fair.

A very successful county nurse with the cooperation of her committee arranged to have the school houses open for a meeting every two weeks during the summer. The children came back to be weighed and measured, and the mothers brought their babies to be inspected. This would be a very convenient means of publicity for the nurse who is planning for the fair.

What the Nursing Committee can do to help:

1. Help to secure interest and money for prizes.
2. Arrange, well in advance, for required space and all furniture and articles needed.
3. Assist in training students who may be preparing plays or exhibits.
4. Help with clerical work which nurse will have to direct.

The school teachers are always willing to encourage their pupils in any endeavor that promotes physical efficiency.

The following suggestions may be helpful in arranging the program of the children.

1. Parade, with appropriate banners, of all pupils who have kept the Health Crusaders Chores.
2. Contest to determine the number of physically perfect pupils in county, with prizes carrying health lessons.
3. Exhibitions of menus and properly prepared, well balanced meals, including school lunches. Exhibits of proper lunch boxes with sample lunches.
4. Roll of Honor of all who have had teeth put in good condition during school year. This should be posted where it can easily be seen.
5. Floats carrying all school children who have had physical examination by physician during year.
6. Demonstrations of first aid, and home nursing.
7. Health posters.
8. Health essays.
9. Health Clown (to be trained during school year).
10. "Sandwich Man" carrying health signs, jokes, etc.

AMERICAN JOURNAL OF NURSING

The December issue of the *American Journal of Nursing* contains an article by Grace M. Cook on the relation of central directories to private duty nurses. No better movement could be instituted, according to Miss Cook, toward professionalizing nurses than the identification of all properly trained and registered nurses.

In the same issue, Clara D. Noyes, of the American Red Cross, gives out figures on Red Cross Public Health Nursing, showing that these services have increased from 155 to 817. To the Red Cross belongs credit for having proved rural nursing to be perfectly practicable.

Details are given of the rapid expansion of a local nursing service developed in a New England town, in which clinics were utilized by all classes of the community under the plan of assigning the charge of a given clinic to a given physician, who then filled it with his patients, being assisted by other physicians. All the resources of the medical and nursing provisions of the community united with the Red Cross in making this work a success. The examination of about twelve hundred children disclosed about four hundred in need of operative care; 193 tonsil and adenoid operations were performed in one week.

*Supplementary to an article on this subject by Miss Fuller, published in the August issue of MODERN MEDICINE.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

PELLAGRA AND POVERTY

THE first reported study in which the degree of the long recognized association between poverty and pellagra incidence is measured in a definite, purely objective manner is that by Goldberger, Wheeler and Sydenstricker,¹ which is presented as the latest of a series of scholarly researches by these authors on the etiology of pellagra.

The study was made during 1916 in seven representative cotton mill villages situated in the northwestern part of South Carolina. In all, 747 households, comprising 4,160 persons, were considered and 97 cases of pellagra were discovered in this group. One of the striking facts made evident from the compilation of the data was that the prevalence of pellagra varied inversely with the size of the family income, this condition being forcibly brought out in the following table:

TABLE 1. NUMBER OF DEFINITE CASES OF PELLAGRA AND RATE PER 1,000 AMONG PERSONS OF DIFFERENT INCOME CLASSES IN SEVEN COTTON-MILL VILLAGES OF SOUTH CAROLINA IN 1916.

Half - month family income per adult male unit.	Total.			Males.			Females.		
	No. of Persons	No. of Cases	Rate per M	No. of Persons	No. of Cases	Rate per M	No. of Persons	No. of Cases	Rate per M
Less than \$6.00	1,312	56	42.7	650	20	30.8	662	36	54.4
\$6.00-\$7.99	1,037	27	26.0	521	6	11.5	516	21	40.7
\$8.00-\$9.99	784	10	12.8	376	4	10.7	408	6	14.7
\$10.00-\$13.99	736	3	4.1	363	0	0.0	373	3	8.0
\$14.00 and over	291	1	3.4	161	1	6.2	130	0	0.0
All incomes	4,160	97	23.3	2,071	31	14.9	2,089	66	31.6

The definite establishment of the correlation between the economic status of a family as measured by the family income and the incidence of pellagra, was but the first step in this study. For more than one hundred years observers have noted a striking relationship between these factors, but it remained for these American investigators to assign a definite and conclusive explanation for this condition.

Other diseases are frequently associated with poverty and the common explanation given is that families in the low income group are handicapped by bad hygiene and sanitation. In the case of pellagra earlier studies by

the same authors indicated clearly that no consistent correlation was found between certain factors of a sanitary character and the incidence of this disease. In the absence of any reasonable evidence that pellagra is an infectious disease it is probably unlikely that the hygienic and sanitary conditions had any effect on the prevalence of this disease. In order to rule out any difference which age and sex composition of the various income groups might have on the incidence of pellagra, the age and sex distribution was studied and found to be practically alike for the population of each economic class.

A brilliant comparison made by the authors of the supply of certain articles of food in households with lowest incomes and in those having at least two cases of pellagra with that household with the highest income, demonstrates that the detrimental effect of low income lies in the character of diet on which the families of the low income groups are obliged to subsist. From the point of view of income the following tendencies were noted:

(1) The smaller the income the smaller were the supplies purchased of all meat (except salt pork), green vegetables, fresh fruits, eggs, butter, cheese, preserved milk, lard, sugar (including syrup), and canned foods.

(2) The smaller the income the larger were the supplies purchased of salt pork and corn meal.

(3) In the households of the various income classes the quantities of the purchased supplies of dried peas and beans, potatoes, dried fruits, wheat flour and bread, fresh milk, and rice appeared without any consistent trend.

It is found that in a general, but quite definite way the food supply of the households of the lowest income class tends to be similar to that of the group of households in each of which two cases of pellagra occurred.

Low family income was not the sole factor determining the character of the household diet as it was found unfavorable conditions regarding the availability of food supplies were also responsible for deficient diet.

JULES SCHEVITZ.

THE CHILDREN'S CODE IN MISSOURI

The Children's Code Commission of Missouri, in outlining its work for the coming session of the legislature, has elected to limit its program to pushing the passage of bills that were not adopted at the Fiftieth General Assembly, and amending some of those which were enacted in order to remove serious opposition and to make necessary changes to put the laws in harmony with recent advancements. Judge Rhodes E. Cave is chairman of the Commission, and Mr. J. L. Wagner is chairman on the Committee on Modification of Laws.

INTERNATIONAL NURSING PROJECT

HEALTH work that knows no political boundaries and is as comprehensive as the needs of the whole people is the objective of the League of Red Cross Societies. The scope of health activities, details of administration, and means for the coordination of the efforts of all organizations as worked out in their several conferences are looking toward the unification of all health programs, looking toward the unification of programs everywhere, with less waste and greater effectiveness being the objective. The objects of the League of Red Cross Societies as stated in the Articles of Association are:

(1) To encourage and promote in every country in the world the establishment and development of a duly authorized voluntary national Red Cross organization, having as purposes the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world, and to secure the cooperation of such organizations for these purposes.

(2) To promote the welfare of mankind by furnishing a medium for bringing within the reach of all the peoples the benefits to be derived from present known facts and new contributions to science and medical knowledge and their application.

(3) To furnish a medium for coordinating relief work in case of great national or international calamities.

Miss Alice Fitzgerald, Chief of the Department of Nursing of the League of Red Cross Societies, in a recent report, stated that the Public Health Nursing Project was "to awaken the people of the thirty-one countries now members of the League to a sense of their own obligations, to create a demand for public health nursing, and to stimulate each national Red Cross Society to assume an important part in these efforts. These are all steps in the right direction, but our service cannot end here. With the history of the public health nursing movement in the United States of America before us, we have an example which should be of the greatest assistance to us, as it is reasonable to suppose that, allowing for differences in nationalities, traditions, customs, needs and resources, the problem to be met in all the countries, and the methods to be adopted for their relief will be necessarily very similar in all cases. Many countries are facing some or all of the following problems: tuberculosis, infant mortality, ignorance of prenatal and post-natal care, inadequate hospital service for the sick, lack of supervision of the health of school children, lack of the most elementary knowledge of personal and home hygiene and of first aid of all sorts.

In dealing with these problems, each country will need the help of the trained public health nurse, and this nurse, on whom such a great responsibility will rest, must be provided with special training to fit her for her task. This training cannot be obtained in the countries which are just instituting public health campaigns and, unless the League is able immediately to come forward at this particularly suitable time and arrange to provide for this training, our world wide dream for the prevention of disease and the betterment of health and general welfare cannot take its first step towards becoming a reality.

It must be only a question of time before an international training school for public health nurses will be established in connection with the League. The main points of the scheme have been discussed and can be stated as follows: Such a training school for public health nurses must cover instruction on the following subjects: Child welfare, including prenatal care; tuberculosis nursing, including care and prevention; general medical nursing, as dealing with contagion, epidemics, prophylaxis; and general educational subjects, such as sociology, psychology, domestic science, dietetics, sanitation, housing, hygiene, the study of the administration of charity, city and state organizations, and other institutions in general. These subjects would have to be taught by experts in each line through courses of lectures.

In addition to these theoretical subjects it would be necessary to provide field work by affiliating with organized dispensaries, visiting nurses' associations, school nursing associations, settlements, industrial nursing activities, milk stations, and, where possible, country and rural nursing organizations. This outline is an average one

and our best schools in public health nursing offer courses in all these subjects.

Miss Fitzgerald's plan for a school was accepted by the Governing Board and nineteen students from eighteen

Katherine M. Olmstead, R.N., editor of Public Health Nursing, MODERN MEDICINE, has been appointed associate director of public health nursing for the League of Red Cross Societies.

countries are now enrolled in a course being conducted in connection with King's College, London. Later the League will establish its own training school. After the graduation of this first class the school will add to its staff field secretaries whose duty it will be to travel extensively, visit, and offer assistance to the graduates in their own fields, thus keeping up the points of contact between the League and the different countries, and securing students for the school.

Miss Katherine Olmsted, department editor on MODERN MEDICINE, has accepted the position of Associate Director of Public Health with the League and will leave early in February for Geneva, Switzerland. Under her direction and with her assistance public health nursing organizations will probably be formed in the following countries: Argentina, Australia, Belgium, Brazil, Canada, Chile, China, Cuba, Czecho-Slovakia, Denmark, France, Great Britain, Greece, Holland, India, Italy, Japan, New Zealand, Norway, Peru, Poland, Portugal, Roumania, Serbia, South Africa, Spain, Sweden, Switzerland, Uruguay, and Venezuela. Students will be selected from these countries and trained to continue and supervise the work in their own countries.

The wide experience of Miss Olmsted in executive capacity in connection with public health nursing projects both at home and abroad bespeak the quality of service to be expected of her in this new capacity. She will continue as editor in chief of the Department of Public Health Nursing in this magazine, thus affording the readers of this magazine a wider outlook in this field.

HEALTH NURSING INSTRUCTION IN DAKOTA

Some time ago the Regents of Education of South Dakota officially established a school of Post-graduate Instruction in Public Health Nursing for the benefit of graduate nurses who wish to take up this branch of nursing. Miss Margaret Hughes, of New York City, was elected director of this department. Miss Hughes is a graduate of the Boston City Hospital, a post-graduate student of the Phipps Institute, Philadelphia.

THE PUBLIC HEALTH MOVEMENT IN THE LIGHT OF MODERN PSYCHOLOGY*

By DONALD B. ARMSTRONG, M.D., AND EUNICE B. ARMSTRONG, M.A., FRAMINGHAM, MASS.

BEFORE returning to an analysis of the psychological factors utilized in the success of the Red Cross, it may be useful to make our generalizations concrete by some illustrations of the conscious utilization of a few of the strong but often unsatisfied instincts. Many are the examples that could be chosen from modern industry. When the health worker-to-be studies the human material upon which his success depends as closely as does the modern employment manager, there will be more illustrations from the health field. The worker who uses this new psychological theory instead of his head will fail as completely as the man who thinks that the ability to do psycho-analysis is "born in one," or "a matter of common sense," any more than is ability to do a urinalysis.

It is impossible completely to understand the human heart either from the inside or the outside, but it is safer to take a chance with the light of some knowledge turned on than to leap in the dark as we do now. Before the leader in health can understand and use the motives of others he must have learned to understand and pierce the disguises of his own motives. It is not at all impossible for the man in charge to avoid unconsciously the possibility of able cooperation simply through failing to analyze his own desire. Perhaps the ideal head of the local committee would be the brother of a woman who has snubbed the executive. It is impossible for him often to believe that any relation of a person who failed to appreciate him can be either able or desirable. Again, the natural preference for doing only the work he does well or easily may hamper an executive. His vanity and desire for praise will unconsciously prevent him from speaking in public, however important that may be, if he does not do it well. His desire to maintain his authority will prevent the delegation of a conspicuous task to someone else, because of the necessary implication that anyone can do anything better than he, the leader. But no matter how completely a man knows his own motives, or how sympathetic he is with the motives of others, there will remain the eternal obstacle to health of human inertia. Most men prefer to be ill rather than to know it. Small-pox immunization seems to perpetuate itself as the battle against hookworm does not. Perhaps this is because the inertia of hookworm is by no means wholly unpleasant to the unconscious self, while the disfigurement of small-pox arouses an emotional response by its menace to the instincts for distinction, for love, and for beauty.

The humility which comes from an understanding of infinite complexity of human motives is perhaps the first step in the training for cooperation. An example of com-

The human mind reacts according to mental laws that are universal. Prediction can be made as to the possible range of response to be elicited when conditions are known and under control.

With a nice adaptation of appeal, the suggested idea carries with it a picture of the end of the act which automatically tends to complete itself.

Mass action is rarely to be obtained on a rational basis. To state the need of a starving child creates no such appeal as to present its picture. Abstract thought lacks the dynamic energy of emotional impulse. Hence the necessity of an emotional appeal to call forth prompt motor response.

When preliminary work in campaigns takes into consideration what may be accomplished and sets itself no task psychologically impossible, a more uniform result will mark our organized efforts.

plexity was the case of a woman who made much trouble about what volunteer work she should perform in the local Red Cross during the war. She had been an able stenographer, but she "simply could not do clerical work. It seems too easy, too little of a sacrifice." Larger factors involved were that the gray veil of the clerical worker was unbecoming, and that the typewriter itself reminded her of days whose social status she wished to forget; but neither could she make bandages. She was "too sensitive to the terrible suffering they represent." A

larger factor was that the social leaders in her town concentrated on refugee garments and she was interested in the work chiefly, though unconsciously, as an opportunity to increase her "society" connections. There was also a definite dislike of bandages because her husband, whom she had hated, had died of wounds in France and bandages reminded her of him whom she wished to forget. There was, however, beneath all these, the real reason why she had to work on refugee garments. To reach that work room she passed the desk of the Chapter vice-president at the hour he spent there; she had been for years in love with him and hoped much, though unconsciously, from her freedom and her proximity.

The complexity of the individual motive is no greater and is often identical with that of groups. The hearty cooperation of a whole body of school teachers may be enlisted if working for a health program incidentally gives them opportunity socially to meet unmarried men. Any small group of aliens or "inferiors" may often be won by giving them the chance to show their likeness to their fellows. Liberty bonds were sold, Young Men's Christian Association millions were raised, partly by the appeal to a man's desire to do as his fellows.

The Instinct to Dominate

In a democracy, custom does not allow us to say much more than "I'm as good as anybody," with the distasteful implication that "anybody is as good as I." This thwarts the primitive desire for distinction, sometimes called "the will to dominate." Everyone really wants to say "I'm better than anybody"; but society refuses to allow this, and so we must satisfy ourselves with praise from others. This is annoying, because it implies effort to earn that praise, and the instinctive man wants satisfaction without effort; however, his need for praise is so driving that he will even work hard to get the praise custom does not allow him to bestow on himself. The bad boy deplored by his parents gets praise from his fellows for his badness. It is the praise that matters, not what the praise is for. A man would rather be known as a trouble maker than not known at all.

*Part 1 of this article appeared in the December issue.

The bearing on the situation of the unconsciousness of the motive cannot be overemphasized. The Lady Bountiful who has provided milk stations in a town often becomes hostile to the official agency that takes them over. She justifies her hostility on the ground that the new work is badly or extravagantly carried on. The fact is, she did not crave health for children, but praise for herself, and praise must be provided if her usefulness is to continue. The same is often true of the benevolent employer. He dislikes the development of trade unions because their sick benefits deprive him of the gratitude and praise he desires. But he rationalizes his dislikes as a belief in the freedom of contracts.

The best executive will often be the man who makes the plan and then acts merely as the instrument to distribute jobs and praise. By identifying a man or organization with the work he is doing and then praising the work, you can give him, in a socially useful way, the praise he must have and you can at the same time get good work done. A man will project himself on to anything in order to get praise. If nothing better offers, he will accept the prize his baby takes in a baby contest as praise of himself. Incidentally, prizes gratify the will to dominate because they serve as a permanent token of superiority.

Industrial conditions do not give the average man sufficient chance to stand out among his fellows in his working hours. A program should take this into account and utilize chairmanships and even memberships on numerous committees as a means of satisfying, for the undistinguished man, the desire for distinction, thus gaining emotional approval for health work as a whole.

The Self Feeling Contrasts

A man will do as much to avoid the feeling of inferiority as to gain the feeling of superiority. Nothing should be done which will emphasize inferiority and thus balk the will to dominate. Sick people fall back on the extreme badness of their condition in their desire for distinction. Intelligent treatment of sickness will emphasize the gain rather than the low condition. A patient will follow treatment for the sake of praise for making progress more than for the sake of the actual progress itself.

A humiliated person or a neglected or criticized group will devote all its desire-for-distinction instinct energy in seeking revenge. Discourtesy in asking questions for records, roughness in physical examinations, keeping people waiting or standing in line, cause an intolerable sense of inferiority. This is the danger to the social structure of "insolence of office." A "fresh" office boy can arouse hatred of a whole organization, for it is intolerable to self-love that a person low in the social scale should be able to wound us. Thence the transference of hatred of the subordinate to his organization. This makes obvious the danger of any public reprimand, or of ridicule, however justifiable and well done. Nor is ridicule of a third party safe, for ridicule creates the dread of ridicule.

Punishment may keep a child from repeating specific bad acts; it will not create the will to do good ones. Cooperation means a positive, not a negative result. There is a psychological economy in the "Resist not Evil" method.

The avoidance of affirmative inferiority is the justification of sinecures. In a case where his good will is important, and a man cannot be used where he is, if possible avoid discharging him; don't demote him, but promote him. It costs less than to fight his unconscious desire for revenge. Often, too, the executive's preference for discharge simply denotes that he is unwilling to be put

in the wrong and is merely expressing his own desire to dominate. An executive who is willing to be in the wrong can get more work done than the just and righteous man, at Versailles or elsewhere.

In gaining cooperation, it is less important to persuade your fellows to like you than to persuade them to like themselves.

It does not hurt to be inferior in one field if you have a chance to demonstrate your superiority in another. The pretty woman does not resent the homely woman's brains. The expert is disliked because he uses his knowledge to humiliate. The expert should see to it that the men he instructs know more about something than he does, even if it be only baseball scores.

It was not the actual improvements which the experts of the Mitchel administration in New York City accomplished that made them hated and lost the "Reformers" their re-election. It was the superiority and the expertness of the expert that made him hated. Then, too, the very word "reform" implies both adverse criticism and an attempt to interfere with a man's delightful and habitual inertia. Had the Mitchel administration sacrificed some of its achievements to letting the average man share in the plan-making and in the credit for the achievements, the idea of reform might have been disinfected; instead, the administration balked the distinction desire in others, while catering too fully to its own desire for distinction.

On a smaller scale the same hostility was aroused in certain Red Cross offices, where the new man in charge took down all the office partitions, removed all the name plates and titles and substituted a "democratic environment." The assistant secretary, lumped with the filing clerk, was no more angry than the assistant secretary's secretary, lumped with "the whole bunch of stenographers." The whole force devoted its energies to annoying the man who had decreased their opportunity for distinction. Yet the conscious reason found to explain the resentment was that it was "harder to work in a big, noisy room."

Resentment of arbitrary discrimination is another phase of this desire for distinction. Any possibility that Catholics or Protestants or Jews or Negroes or ministers or laboring men should think that they have been left out *as such*, should be avoided. Women should almost have been included in the above, for leaving women off committees is now beginning to be felt an arbitrary discrimination, implying not merely the natural thing, namely, that they are women, but rather implying that they are inferior.

To avoid balking the desire for distinction, it is important not to ask a man to do something at which he will fail. Public speaking for foreigners without much English is a humiliation. Making written reports and filling out questionnaires are irritating to a man who can maintain his feeling of superiority until he has to spell. He will tend to pick himself up by ridiculing the whole project of which the questionnaire becomes the symbol to him.

Apparently, attempts at coordination in the health and social field, prevention of overlapping, etc., which sound so reasonable, often arouse the most intense antagonism. Probably this is due to the unconscious recognition that in an orderly and disciplined whole there cannot be so many heads and sub-heads. Understanding of this problem will allow the old titles with their distinction-conferring value to survive even the completest reorganization. A small staff may do the work, but the lady presidents and the honorable chairman will provide the emotional approval based on one's own glorious participation, the glory of personal leadership.

This desire for distinction is often the underlying reason for demands for more money, rather than the desire for extra comforts. Money is with us the measure of a man. To measure a man in terms of service will tend to socialize this instinct for distinction.

Desire to Create Instinctive

Other instincts we shall treat in much less detail. The instinct to create is too often confused with the sexual impulse. The instinct to create, though often allied with sex, is not identical; it is rather the instinct of self-expression. Offspring is the fundamental expression, but mental offspring are real creations, too, and the creation of health may satisfy the desire to procreate mentally, which our present wage system too often disregards. In order to give men the opportunity to construct and create, it may be well worth while to subordinate speed and efficiency. What a man builds, he loves. Even though the man at the top can make better plans in a morning than a committee can make in a month, he cannot afford to lose the cooperation he can gain by satisfying the instinct to build. But he doesn't have to use the committee's plans. Men love to make plans because they thus express themselves, and they will work hard to carry out a plan which they think is their own. The desire to create is linked with a desire to do good work. If the instinct to create is stimulated, men will attend conferences on method, read books, etc., in order to satisfy the desire to build well—which is the instinct of workmanship. A superimposed program balks the instinct of self-expression. A man may think of his fine contribution, even though it may have been only hanging an exhibit; and he will support the whole health plan for the sake of his bit in it. The idea that we must reward the man we ask to make plans is nonsense. He is in his little way an inventor, with an inventor's ecstasy of self-expression, and a prize is less of a stimulus than the mere opportunity to build.

Love Instinct Is Dynamic

The love instinct is by far the most vigorous and forceful. No instinct is more complexly woven through all human acts, and it should be utilized in health work. Many patients get well to please the doctor. Much good work is done to please the chief, especially if he is attractive and his subordinates are women. But such love expression is not alone utilizable. The love of a leader satisfies the love instinct. It pays to put at the head of a committee someone who has the affection of his fellows. The younger, less mellow, better trained man may have to do the head work; but the beloved leader can arouse energy as he cannot. The aspect of the instinct to love which health work can especially satisfy is the love of one's children and their posterity. A man who follows no rule of health, because for himself he is willing to take chances, will carry life insurance for his beloved ones. Indeed, insurance policies are not sold rationally, but emotionally. The very union leader who for one reason or another is fighting medical inspection for himself is insisting on school medical inspection in Pennsylvania. The health program can attach to itself much of the force of parental love by warmly picturing good breeding, environmental infection, and infant, pre-school, and school nursing. The success of the "War to End War" appeal is a good example of this.

Must Reckon With Fear Instinct

An instinct which present conditions fail to satisfy and which social plans can wisely take into account is the fear instinct. This is really the desire to feel fear, and

should be distinguished from the flight instinct. The opportunity to feel fear was so amply provided for man in the cave days that he acquired through habituation a desire or instinct to feel fear. The desire for adventure arises as an expression of this instinct. Stealing apples, running in front of automobiles, and telling ghost stories, all show the child's fear instinct. The average adult working man has all too little opportunity for adventure. His wife has less. The popularity of the "suicide jobs" in the steel plants may not be due wholly to their high pay. The man who refuses to use the guard provided for his machine is satisfying his fear instinct. The tramp riding blind baggage, the reckless automobilist, the big game hunter, the roller coaster fans, all show the craving of fear. The so-called fear of sickness, of old age and unemployment is an anxiety rather than a fear. The preparedness propaganda, and the present anti-Red propaganda both owe a considerable measure of their popularity to their satisfaction of the craving to fear.

Loyalty as a Motive

Such satisfactions of the instinct to fear are either useless or undesirable. The point is that some satisfaction seems essential. It is inaccurate to say that working on machines is dangerous and therefore constitutes adventure. The man who guards the roller coaster as a job no longer finds riding an adventure. We must remember that the civilized man can get satisfaction from mental as well as physical adventure. Presiding at a health meeting, reading a report in public, even sitting on a platform; being put in command of a piece of social work; arguing or conflicting with a superior; or merely speaking to the big man at the head—these things give a thrill of fear and constitute adventure for many men and for more women. Such exciting, adventurous jobs should be distributed as widely as possible. There is a mistaken tendency to leave all such things to the "proved man."

The motive power of the instinct of loyalty is invaluable. The "we" feeling makes men work together best, and working together creates the "we" feeling. The importance of bringing together the different men engaged in a piece of work is great. Cooperation means good team work, and this you can't get if the members of the team never see each other. Conferences, committee meetings, mass meetings, all have their justification in their emotional rather than in their intellectual product. Training quarters have their psychological as well as their physiological value. The common meal, the common possession, likewise inspire loyalty. A beautiful building dedicated to health or a health room furnished by common subscription helps to satisfy the instincts for loyalty, for an ideal, and for beauty. Perhaps this is one of the chief values of the Health Center. Churches need their own buildings to hold the congregations together. Health requires its own outward, visible symbol. A common danger creates loyalty. Let a man know the factors he is fighting: let him feel that the battle with the death and sickness rates is his battle. A common experience likewise creates the "we" feeling and so serves the instinct of loyalty. Canvassing for funds has a distinct value in itself, whatever the intake may be.

Finally, let us consider the success of a conspicuous community group, the Red Cross, in obtaining funds and cooperation in its relation to these instincts.

(1) The desire for distinction was widely gratified. The largest giver, the fastest cutter, the neatest worker, the cleverest canvasser—all gained distinction. Extensive opportunities were provided for "nobodies to be some-

bodies." The somewhat military atmosphere of the Red Cross as well as war-time itself gave opportunity for the exercise of authority highly satisfying to the will to dominate. Praise of the work of the local chapters was generously administered and the individual workers basked in that praise. Many women, especially, were given for the first time positions of leadership which inspired them to do well, in the bright light of publicity turned on their endeavors.

(2) The instinct to create, to express one's self, was somewhat unnecessarily balked and the criticism of autocracy still survives. Opportunity for fundamental participation was relatively slight. There was little cooperation in the plan-making on Mt. Sinai. But this was less objectionable than a similar implication of inferiority in peace times, because of the number of free Americans who were saluting other free Americans. There was considerable compensation in the fact that the workers and chapters were shown the goal sought and their part in reaching it. Most of all, there was opportunity for real participation in the work offered to every man, woman, and child.

(3) The fear craving was largely satisfied. To some women the mere doing outside of the home the identical work to which they were accustomed was adventure. To others collecting funds in public places, to others speaking as delegates in sectional conferences, was not effort but excitement. The sign in the workrooms, "A thread left on a bandage may cost a life!" made working thrilling.

(4) The instinct to play, which the war spirit balked, was encouraged by the Red Cross. Dressing up in veils was partly playing. The entertainments justified by being "for the benefit of the Red Cross" gratified the instinct to play.

(5) The instinct of loyalty was tremendously utilized. Aside from the obvious appeal to loyalty to one's soldiers, one's country, and one's ideals, there were minor but more intimate opportunities for gratifying the loyalty instinct. The common workrooms had a spiritual as well as a utilitarian value. The wearing of a button, and more especially the wearing of a uniform in a time of uniform-wearing, gratified the desire to be like one's fellows. The same was true of the display of window and shop cards.

(6) The instinct to love was obviously given an intense gratification. Socks were not merely work, they were love itself; and the possibility of some outward expression of love was very gratifying at this time of intense emotional strain. Every war appeal contains directly or indirectly an appeal to the love instinct. "Work or give to make your children safe"; "The Greatest Mother in the World," were fundamentally satisfying appeals.

(7) The instinct of self-preservation was of course implicit in all war appeals.

(8) The repeated opportunities to give gratified the desire for self-sacrifice.

(9) The instinct of pity was especially reached both by the work of the Red Cross and by its best posters. It is noticeable how much pictures of sick or maltreated children are used in various educational exhibits. Also, the movies, as, for example, "Broken Blossoms," show the pleasure that results from feeling pity.

(10) The instincts for worship, for an ideal, and for beauty were gratified. The great ideal of service to friend and foe alike satisfied the much thwarted desire for an ideal. The advertising of the Red Cross was in itself beautiful, as were its parades and pageants. The uniforms were beautiful or thought to be so. These may

have served a similar purpose to ritual garments in religious exercises, and so have enlisted the instinct to worship.

(11) Nor did the Red Cross fail to utilize selfish desires. Pugnacity was given full opportunity for expression in the competition in work for funds, with other teams, other shops, schools, towns, and states.

This is but the casual running over of the appeals to a few instincts made by propaganda which succeeded. It may well be suggested to check up, as a matter of routine, any health program before attempting to put it into effect, with these two questions: (1) What instincts are balked by this program? (2) What instincts are satisfied by this program? With these inquiries as a basis, and with a rational use of applied modern psychology in practical health work, it is confidently believed that the future will hold, for health activities, an ever increasing assurance of successful service and accomplishment.

TO AID IMMIGRANT WOMEN

The World's Committee of the Young Women's Christian Association, with headquarters in London, is planning the appointment of an International Immigration Secretary whose office it will be to correlate the work for immigrant women now being done by the Young Women's Christian Association in many countries and to develop new lines of service. The aim of the new department will be to get in touch with women and girls traveling from one country to another and through the Association representatives in the various countries to keep in touch with the travelers, in order to give any necessary help, from the time they leave their own country until they have reached their destination. A secretary from the United States is to be appointed to the office.

A MODERN PEDIATRIC SERVICE

The more important elements of the organization of a modern pediatric service are analyzed in an article by Dr. Henry Heiman in the November issue of *Archives of Pediatrics*. Such a service should form an integral part of a large modern hospital and should include the infants' and children's wards and the out-patient department. Especially should the out-patient department be thoroughly organized as a means of extending greater opportunities for the diffusion of social and educational work in child hygiene and preventive pediatrics. A complete pediatric service of this kind should include the following functionaries: a pediatricist to the hospital, one associate, four adjuncts, sixteen senior assistants, sixteen junior assistants and an indefinite number of clinical assistants. Nutrition classes are included in the scheme. Pediatric classes for the routine of children of the pre-school age and a division for the correction of remedial defects are needed, and special facilities for the study of protein sensitization should be provided for cases of bronchial asthma, hay fever, urticaria, and eczema. It is only through balanced organization that it becomes possible to realize fully the possibilities of pediatric service.

WHITE LIST OF HOSPITALS

The American College of Surgeons has just published a list of hospitals having one hundred beds or over which have been rated as efficient to the extent that they have complied with certain minimum standards laid down by the college. In the United States and Canada 692 general hospitals have been visited by agents of the College. The White List, including 377 hospitals, is available.

A STUDY OF DISPENSARY PATIENTS

A REPORT BY THE PUBLIC HEALTH COMMITTEE OF THE NEW YORK ACADEMY OF MEDICINE

THE small percentage of reported poverty among those applying at the Lincoln and the New York Hospital Dispensary is surprising. Of the ninety-seven applicants interviewed at Lincoln Dispensary, only two claimed lack of money as the reason for applying, and at the New York Hospital Dispensary only one applicant out of fifty-two gave poverty as a reason. Among this indigent group, 77.1 per cent were women and children and 22.9 per cent men. According to racial distribution, the Slavs were most numerous in that group, 24.2 per cent of the Slavs giving poverty as the reason for seeking dispensary aid. Of the Irish, 21.2 per cent; of the Italians, 18.1 per cent; Negroes, 18.8 per cent; Germans, 19.3 per cent; and 12.4 per cent of the Hebrews gave lack of funds as a cause of recourse to the clinic. In all the groups with the exception of the Irish the preponderance was of women and children (Tables VII and VIII). As for other reasons, 5.5 per cent came because they were in need of the services of specialists or of special apparatus; 31 per cent were attracted to the dispensary by its reputation; 7.5 per cent were referred by private physicians; 2.3 per cent, by hospitals; 1.7 per cent, by other dispensaries; 2.1 per cent, by social agencies; 2 per cent, by school nurses; 4.1 per cent lacked confidence in their private physicians; 1.9 per cent came because they were out of work and could spare the time to come for medical advice. In this last group men constituted 55.5 per cent of the total number of cases (Table VII). The percentage of cases giving reputation of dispensary as a cause for their coming is interesting, in that it shows the extent to which the several dispensaries receive the endorsement of their clients. In this regard St. Luke's heads the list, 83.7 per cent of the patients in that institution giving this reason. This was also the reason given by 61.5 per cent of the patients at the New York Hospital

the rest were distributed among the several specialties. The dispensary has ceased to be a place where the indigent come for relief and medicines. The large masses of people have come to regard it as the only institution where the services of specialists can be obtained. In this light the social significance of the dispensary becomes apparent and in this light it must be regarded by the community.

After the general medical clinic, the surgical clinic received the largest percentage of cases, or 15.7 per cent. The eye clinic received 8.9 per cent; the ear, nose, and throat clinic 7.8 per cent; the gynecologic clinic 8 per cent; orthopedic clinic 7 per cent; children's clinic 6.6 per cent; skin disease clinic 6.6 per cent; neurologic 6 per cent; and the large percentage of 7.8 per cent of cases in the prenatal clinic is an indication of the extent to which the clinics take up public health functions. The clinical distribution of the patients of the various nationalities may or may not be of significance. Of all of the Italians, 19.9 per cent were in the surgical clinic, and 14.2 per cent in the eye clinic. This was the highest percentage of any nationality in that type of clinic. The Slavs showed the highest proportion in the orthopedic clinics, the Negroes in the gynecological and prenatal clinics. The Hebrews contributed more than half of the cases to the neurological clinics and more than one-third to the ear, nose, and throat clinic (Table IX).

Conditions Prior to Application

Among the questions asked of the dispensary patient was included the duration of the condition and the manner of its treatment prior to coming to the dispensary. The information gathered indicates that 26.6 per cent of the patients were ill less than one month before application to the dispensary; 11.6 per cent had been ill from one to three months; 8 per cent had been ill from three to six months. In 5.6 per cent of the cases the duration was from six months to one year, and 25 per cent had suffered from the particular condition for more than a year. This would seem to indicate that more than 60 per cent of the cases come for the treatment of conditions of three months' duration or more. Among those with chronic ailments were many who stated that they had received previous treatment, either at the hands of private physicians or in hospitals or other dispensaries; but there remained a considerable group, 21.3 per cent of those ill more than three months, who had received no treatment whatsoever, and 2.4 per cent who had employed home remedies.

In studying the various racial groups with regard to treatment prior to applying to the dispensary, the Hebrews were the least neglected with regard to taking care of their conditions, as only 17.7 per cent stated that they received no previous treatment. The Negroes were among the most neglectful. The number of cases reporting the use of home remedies was very small, a total of eighteen, of whom five were native born, eight Hebrews, two Germans, the few remaining cases being scattered through other nationalities; 18.7 per cent of the cases had received former hospital treatment of their conditions, and 18.3 per cent had been at other dispensaries; 38 per cent had consulted private physicians (Table X).

In order to ascertain the "draining" area of the dis-

Dispensary, 59.6 per cent at the New York Eye and Ear Dispensary, 56.8 per cent in the Northeastern Dispensary, 55.9 per cent in the University of Bellevue Dispensary, 52.6 per cent at Mt. Sinai, and 51 per cent at the Demilt Dispensary.

Distribution by Clinics

The best answer to the question, for what do the patients come to a dispensary, will probably be found in their distribution among the several departments of the dispensary. The distribution of 1,968 patients selected at random in the thirty-seven institutions seems to answer that question in a very emphatic way (Table IX). Only 16.3 per cent of them were in the general medical clinics;

dispensaries of the city, a study was made of the geographical distribution of the patients. The distances were calculated on a bee line rather than in accordance with the possible transportation routes. The distances, therefore, are shorter than the actual length of travel to the dispensary. The table showing the distance traveled by the patients to the clinics is, therefore, only an approximation of the actual dispersion of patients from the dispensary, but may be of service for purposes of orientation. Twenty-four and eight-tenths per cent of the patients lived within half a mile of the clinic; 17.6 per cent from half to one mile; 16.1 per cent from one to two miles; 7.3 per cent from two to three miles; 4.3 per cent from three to four miles; 3.3 per cent from four to five miles; and 22.5 per cent, or the second largest group, lived more than five miles away from the dispensary. The probable reasons for the large number of patients traveling five miles and over to the dispensary are: (1) that the boroughs of Queens and Richmond are very meagerly supplied with medical facilities, and patients from these boroughs to Manhattan must travel long distances; (2) among the patients there are a considerable number of those who either live in the suburbs of the city and come specially for consultations in the dispensaries, or who work in New York and make use of the New York dispensaries; and (3) the special clinics draw patients from all over the city.

By analyzing the distances by types of institutions, we find that among the patients of the college dispensaries 29.3 per cent come from distances more than five miles away, and 37.4 per cent of the patients in the special dispensaries reside more than five miles away from the dispensary. Of the patients at the Neurological Institute, 60 per cent lived that far away, and likewise 52.4 per cent of the patients of the Orthopedic, 51.4 per cent of the Skin and Cancer, 41.9 per cent of the New York Eye and Ear Infirmary, 33.8 per cent of the Knapp Memorial Eye Hospital, and 32 per cent of the Manhattan Eye and

Ear Hospital Dispensary come within that category. One-third of the patients in the Babies' Hospital Dispensary and one-fourth of the patients of the Woman's Hospital Dispensary belong to the same group. Likewise the medical college clinics attract large numbers of patients living far away. Vanderbilt, for instance, has 45 per cent of its patients traveling long distances, and Cornell 33.3 per

cent, University and Bellevue 37.2 per cent, and the Post-Graduate 41.3 per cent. Long Island College is an exception to this rule, only 4.4 per cent of its patients coming from more than five miles (Tables XI and XII).

Patients Opinion of Treatment

Every patient interviewed was asked his opinion of the treatment received in the dispensary and whether his condition was improving. Of 1,225 patients questioned, 62.2 per cent either refused to express an opinion or had come to the dispensary only for the first time and therefore could not give an opinion. Of the remaining 743, 39 considered the treatment poor, 45 judged it as of doubtful value, 26 thought it fair, and 633 said that it was satisfactory.

In view of the fact that only 30 per cent of the patients wished to express an opinion and that their judgment

LAW FOR THE DOCTOR*

By LESLIE CHILDS, Attorney at Law, Greenfield, Ind.

Liability for Performing Unauthorized Autopsy.

A CERTAIN right of property in a corpse is recognized in law as belonging to the next of kin, or other person charged with the legal duty of burial; and the performing of an unauthorized autopsy has been uniformly held to be such a violation of this right as will give the aggrieved person a right of action for damages against the offender.

Generally speaking, then, before an autopsy may be lawfully performed, permission must be obtained of the next of kin or person in whom this right of property in the corpse is accorded. Exceptions to this rule are found in jurisdictions where by statute it is provided that under certain circumstances the coroner, board of health, or other officials may order an autopsy, in which case it follows, if the statute has been complied with, an autopsy may be performed without the consent of the next of kin, and free from liability, if done on the authority of the official or officials designated in the statute.

If the physician making the autopsy proposes to rely on the authority given him by an official, through a statute, he should, for his own protection, satisfy himself before performance that the statute has been strictly complied with. If this is not done, and it develops that the statute has not been followed, the physician may find himself placed in the unwilling rôle of a defendant at the hands of the next of kin.

A case illustrating this point, and the danger involved in assuming that a statute of this kind implies a right to perform an autopsy, was that of *Woods vs. Graham*, 140 Minn. 16, the facts being as follows:

Frances Woods brought an action for damages against Dr. Robert Graham, alleging that he had performed an unauthorized autopsy upon the body of her daughter. The doctor admitted performing the autopsy, without the plaintiff's knowledge or consent, and pleaded the following facts as a defense:

That at the time he was county physician for St. Louis County, and that he attended the daughter of the plaintiff, as a charity case, in her last illness. That after the girl's death, the undertaker in whose charge the body had been placed, applied to him for a medical certificate, as required by law, stating the cause of death; and that, in order to give this certificate, it was necessary to perform an autopsy to ascertain the cause of death.

It was further pleaded in defense, that the autopsy was performed in good faith, in a decent, scientific manner, no incisions being made that were not necessary to accomplish the purpose undertaken. The lower court held that this answer failed to state a defense, sustaining a demurrer thereto, and the doctor appealed to the Supreme Court. In passing on the record, in the light of the Minnesota statute, the Court among other things said:

It is conceded that plaintiff's consent to the autopsy was not obtained or asked for, and that she had no knowledge thereof until after the autopsy was performed. Defendant claims freedom from liability on the ground that it was necessary to have the autopsy in order to discover the cause of death and be able to give the certificate required by Gen. Stat. 1913, Sec. 4652. This section requires the undertaker to obtain and file a medical certificate subscribed by the attending physician stating the disease or injury causing death, with contributory cause or complication, etc. Section 4654 provides that a burial permit shall not be issued except upon the filing of a proper

*The fourteenth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

was chiefly guided by whether or not they were improving, and also because of the fact that the questions had been asked at the dispensary, where the patient did not feel free to express an opinion, the information gathered is not of particular value.

Of the 39 who complained about the treatment, 12 are native born, 17 Hebrews, 3 Italians, 3 Germans, 1 Slav, 1 Negro, and 2 belong to the miscellaneous group of nationalities in our classification. Of the 45 who were in doubt about the value of the treatment received, 5 were native born, 10 Italians, 17 Hebrews, 4 Irish, 1 Slav, 2 Germans, 3 Negroes, and 3 of the miscellaneous group.

pensaries, we found that the largest number of commendation was given by the patients in the institutions devoted to the treatment of special diseases. In those institutions 90 per cent of the patients who were willing to express an opinion considered the treatment given as satisfactory, while in the general dispensaries only 85.9 per cent of the patients disposed to express an opinion considered the treatment good, and in the medical school dispensaries only 81 per cent found it satisfactory. Adequacy is not to be regarded as contingent upon such approval.

certificate of death. Section 4658 provides that no body shall be interred until a proper certificate of death has been filed and a permit issued. Section 4662 provides that any person willfully refusing to perform any duties imposed by the act is guilty of a misdemeanor.

The sections of the statute referred to do not in terms authorize an autopsy to ascertain the cause of death, and we are unable to hold that they authorize it by implication. . . . Gen. Stat. 1913, Sec. 8745, makes it a gross misdemeanor to dissect the dead body of a human being, except in cases "specially provided by statute," or where the direction or will of the deceased authorizes it, or where the coroner authorizes it, or where the "husband, wife, or next of kin, charged by law with the duty of burial, shall authorize dissection for the purpose of ascertaining the cause of death, and then only to the extent so authorized."

It cannot be held that this was a case "specially provided by statute"; as stated, defendant admits that the mother, who was the next of kin, did not authorize dissection to ascertain the cause of death.

The Court thereupon held that the lower court was right in sustaining the demurrer to the answer filed by the doctor. Holding in effect that on the record he was liable in damages for the autopsy performed.

OBSTETRICS AND ANESTHESIA

The National Anesthesia Research Society has issued a "Monograph on Obstetrics and Anesthesia." In its first monograph it gives the historical evolution of nitrous oxid analgesia and anesthesia in obstetrics; the effects of civilization on childbearing women, and the failure of anesthesia and antiseptics to decrease obstetrical morbidity; the study of H. C. Davis in the relative toxicity and efficiency of chloroform, ether and nitrous oxid; Levy's views on chloroform fibrillation and its dangers; and blood changes under anesthesia and analgesia. Pointers are given in the administration of analgesia of anesthesia and statistical analysis of Davis' results, together with a discussion of operation during pregnancy.

MOTHER AND CHILD

The December issue of *Mother and Child* contains a statement of Herbert Hoover, president-elect of the American Child Hygiene Association, on his program for American children. The most practical step yet evolved has been the creation of the community nurse, with the stimulus thus given to community interest in the problems of childbirth and infant care. He sees no less reason why the local governments should not support a staff of community nurses than that they should support a staff of policemen. He expresses himself as definitely in favor of clinical examinations and reports to parents as a fixed part of school work. We cannot, as a nation, rely for the upbuilding of the race upon the initiative of the parents alone, and the physical development of the child must be considered of equal importance with education and carried along parallel with it.

An interesting report comes from Dr. Chester L. Carlisle of a popular educational campaign on child hygiene in Oregon, preliminary to proposed legislation to provide medical and surgical treatment for sick and deformed indigent children, under the supervision of the medical department of the University of Oregon.

The university at the request of the legislature has, without funds, concluded a survey in all fields of mental, social, and child hygiene. Many interesting sidelights on community needs have been unearthed, and in this way remedies are made possible for conditions which are peculiarly of social significance.

Final analysis has not been made of all the material gathered, but the activities stand out as the most ex-

tensive undertaking handled in this matter, and, when completed, will present all essential facts on mental defect, delinquency, and dependency as found in Oregon's every day community life.

SPECIALISTS IN OTO-LARYNGOLOGY

That a lack of proper special education on the part of those who claim to be specialists in oto-laryngology was at the bottom of the difficulty experienced by the Surgeon General in attempting to secure for the American Army a service in this specialty, is the finding of a committee appointed to look into this subject, representing the American Medical Association and all the societies in America who are connected with this specialty. The recommendations of the committee, just published, present as a minimum requirement:

(1) As a preliminary basis for special education in oto-laryngology, four years practice as a licensed practitioner, or one year's internship in a Class A general hospital.

(2) The standardized requirements as outlined in the Report carried out in the post-graduate department of a university, occupying the candidate from four to five hours daily for a period of six to nine months, the remaining portion of each day preferably to be spent in attendance on an out-patient clinic in oto-laryngology.

(3) Internship on this special service to be not less than sixteen months.

The Committee is representative, the work constructive, and is aimed to remedy a shortage which has appeared in this field. D. J. Gibb Wishart, of the University of Toronto, is chairman, and Thomas J. Harris, 104 East Fortieth Street, is secretary of the Committee.

PUBLIC HEALTH IN CZECHO-SLOVAKIA

The International Health Board of the Rockefeller Foundation has announced a cooperative program in public health agreed upon with the government of Czecho-Slovakia, which includes the lending to the Czecho-Slovak government the services of an American competent in public health administration, fellowships for the training of a select group of young Czechs for service in the field of public health, cooperation in the development of a national public health laboratory service, and financing a Czech commission to study public health administration in the United States and England.

Nine medical representatives are pursuing courses in public health, hygiene and preventive medicine at this time and five members of the Commission from the Ministry of Hygiene of Czecho-Slovakia have recently arrived in America as guests of the Foundation. They are: Dr. Vladimir Basika, chief of the Medical and Sanitary Department of the Ministry of Public Health of Slovakia; Dr. Brhumil Vacik, general medical health director in Brno, Moravia; Dr. Ivan Halek, Member of Parliament and general medical director in Bratislava, Slovakia; Mr. Antonin Kolinsky, general director of administration and finance in the Ministry of Public Health, Praha; and Dr. Vladimir Petrik, medical health inspector in Bratislava, Slovakia. Their tour will include visits to Baltimore and Washington, scenes of rural health work in North Carolina, and Boston, Albany, Saranac, Toronto, Chicago, and Columbus.

A third factor in promoting human wellbeing and human good is health—health, individual and health, social or community.—James H. Harris.

PROTECTION FOR DRUG USERS

SPECIFIC action in a given disease has been demonstrated for comparatively few drugs. The man of science is always observant of the way in which drugs influence the vital processes. It is to him of the utmost importance that the drugs he uses be certified as to strength, age, and purity; for uncertainty in such essential matters not only spells defeat in the individual case under treatment but renders valueless the most painstaking observation on all scientific aspects of the question. It is for this reason that so much effort has been made to regulate by statute the vending of drugs, and to provide by inspection against adulteration or their deterioration on the shelves.

The layman is more credulous as to the diverse curative properties of drugs and is more prone to accept adulterated products from vendors of drugs and to indulge in the use of patent nostrums for self diagnosed diseases—a

Keystone View Company.

The learned druggist on the corner does not escape the drug inspector sent out by the Board of Health. The food drugs in the 2,600 drug stores in New York City are examined regularly by inspectors to see that they are unadulterated and fit for medicinal purposes.

practice which in a more enlightened era will be prevented by law.

The subject of supervising drugs as to their proper labeling and purity, patent medicine as to extravagant claims, and of package goods for deteriorations, is the proper concern of health boards everywhere. Men who have made life long studies of the subject are the only ones who are in a position to give trustworthy advice as to distributing and dispensing drugs.

The control of drugs, therefore, becomes an important public health problem. Their inspections become a national work with official recognition, thus affording protection for the exacting physician, safeguarding the unintelligent self-administration of drugs by the layman, and saving from himself the helpless narcotic addict.

Perhaps the chief advantage of the systematic supervision of drugs lies in the direction of the control of patent nostrums. The man of science has a reasonable margin of safety. What he does not know of recent laboratory tests he is in a position to learn, and he is further

Keystone View Company.

Even the patent medicine users are protected by the Board of Health. Drug inspectors make constant examinations of the shelves of druggists to find patent medicines in which extravagant claims are being made—and these medicines are weeded out.

safeguarded in not expecting too much of drugs, per se, as the remedy for human ills. The person who readily accepts the large promises of the patent medicine man is the chief beneficiary of a system of inspection which has taken off of the market many harmful, often habit forming drugs that masked themselves as cures. A further step in the direction of the relief of the evils of self-medication would be in the dissemination on a large scale of information on abuses of this kind, and of what may reasonably be expected of drugs, and what drugs are safe in the hands of the general public. Prevention rather than cure should be the popular slogan. S. P. M.

Keystone View Company.

This Committee appointed by the Commissioner of Internal Revenue is segregating the narcotic drugs sent in from the various government offices. The unopened and original packages are turned over to the Public Health Service for use in Government hospitals. Broken packages and adulterated drugs are destroyed. Approximately one million dollars worth of drugs have been sent into Washington during the past year.

RADIUM IN THE SAFETY MOVEMENT

The Radium Information Service of New York has recently issued a statement concerning the use of radium as a new element in the safety movement. "Radium's rôle in industry as a life saver is less spectacular but perhaps even more important than it is as a therapeutic agent," says the statement.

The great mass of accidents in factories, in mines and in other industrial institutions where darkness is a creator of danger, are being eliminated through the newest invention of science—radium luminous material. Radium illuminated watches are familiar articles. The same material that illuminates these is now being employed in great factories on all power line switches where fumbling might mean electrocution to the operator.

High pressure gauges, which are installed as an insurance against dangers, are deprived of a great deal of their safety value through inconstant lighting. Their dependability as indicators is increased tremendously through making them safe twenty-four hours a day by the application of radium luminous material, which is invariably luminous in the dark. Steam gauges and water gauges of all sorts are making use of radium to increase safety.

Electric switches are often set in places which are unlit. This includes electric lighting equipment which is usually visible only after the light it controls has been turned on. A spot of radium luminous material on the bottom or switch makes them easily located in the dark, so that in emergency they may quickly be made use of.

Likewise, a fire alarm or a fire extinguisher is deprived of much of its efficiency through being invisible in the dark. Radium luminous material acts as a quick locator for them. Telephones, which are often necessarily found quickly in the dark in emergencies, various emergency call bells, and revolvers are made more useful through the application of undark. Gun sights, illuminated, insure accuracy of aim in the dark. The need of luminating poison bottles, so that they may stand out warningly in the dark has been demonstrated too often to need further dwelling on. An interesting safety device is the safe combination whose dial is radium luminated, so that no artificial light need be used for it.

The industrial uses of radium luminous material are many. Bolts that are necessarily attached to the dark under portions of machines and equipment are being touched with dabs of this luminous material, with a consequent great saving of bloodshed. In mines where the carrying of oil lamps or the placing of electric lighting equipment is not feasible, radium has been found to be a boon to humanity. There are dark corners in the dark underground channels which miners must traverse, corners where danger lurks—these are made safe through the unvarying luminosity of radium.

The value of radium to mariners is commencing to be recognized. Not only the compass dials, but the steering wheels, the gauges, and other instruments which should be instantly and uninterruptedly visible have been touched with radium. Motorists, motorcyclists, and the operators of any machinery which has indicating dials, or gauges which tell of the speed of the motor or the quantity and mixture of fuels and oils, are finding the solution of their difficulties in radium luminous material. The hazard and uncertainty has been reduced.

While radium is the most valuable element in the world—a gram of radium, which is about a thimbleful, costs \$120,000, as opposed to \$150 for an ounce of platinum—so powerful is it when mixed with other materials that

even the minutest particle is effective in making material self-luminous for years. It is this quality which makes radium luminous material commercially possible.

The great value of radium is due to its scarcity, and to the great difficulty in isolating it after it has been found. Much of the radium of the world is now found in America, in carnotite fields. A great portion of this comes from the Undark Radium mines in the Paradox Valley of Colorado.

The ore is found in narrow seams in the ground. It is sorted and packed in one hundred pound sacks and transported sixty miles to the nearest railroad station on the backs of burros and mules. Thence it is shipped in carload lots 2,900 miles across the continent to an extraction plant in Orange, N. J.

The power of radium lies in the penetrating character of its rays, which disintegrate and travel at the rate of three thousand miles a quarter of a second.

In addition to the use of radium luminous material on machinery in industrial plants, it is used extensively for the marking of any corner or spot which should be visible in the dark. Angles of tables and chairs, corners in rooms, numbers to indicate cubby holes or doorways on which there is no other illumination are touched with a spot of undark. Even the valuable electric torch increases its efficiency when it has a touch of radium on it so that it can be reached instantly in an emergency in the dark.

When other lights fail, when fuses blow out, wires break down—radium will glow dependably without danger of explosion or of burning.

The employment of radium to help solve our medical and industrial problems of life safety is as yet in the first stages of its development. What the future will bring no one knows.

THE SUBNORMAL IN INDUSTRY

The significance of Joseph Choate's statement that "the trouble with the feeble-minded is that there are so many of us," is appreciated when, according to United States Army figures, the estimated number of feeble-minded in the United States would run over half a million,—an aggregate so large that it is apparent the state can never adequately care for its feeble-minded until there is a definite state policy looking toward their self-support.

A recent bulletin of the New York State Industrial Commission reports on the success of the experiment in rendering feeble-minded workers self-supporting while they are segregated there under supervision at Oriskany Falls, N. Y. From the Sonoma State Home in Eldridge, Cal., has come the only experiment reported which derives an efficiency quotient for such subnormal workers. The average earning capacity of four groups is 46, 55.9, 65.0, and 72.0 per cent, respectively, as compared to normal workers.

The introduction of subnormal workers into industrial life must be scrutinized, according to the New York recommendation, from the following viewpoints: (1) The welfare of the girls themselves; (2) the effect on their fellow workers; (3) the relationship of such plans to the interest of the public in the extinction of the moron type.

They conclude that it is open to question whether the state should adopt a permanent policy of placing workers known to be subnormal in private industries to compete with normal industrial workers. The problem of rendering the fundamentally irresponsible self-supporting must somehow be made compatible with the interest of normal workers and of society as a whole.

FATIGUE IN THE BOOT INDUSTRY

A preliminary note has been issued in Report No. 10 of the Industrial Fatigue Research Board of England on output data as related to fatigue in the boot industry. Daily reports were compared of individual members of working groups and the conclusions based upon them.

Where two or more records are available for the same operation, the more highly skilled operative has a more regular graph and shows less inclination to fall off toward the end of the week than the operative with a lower average output. . . . Where a workman is comparatively unskilled or ill suited to his job, his output curve tends to be irregular or to drop as the week passes, whereas the skilled operative, employed on congenial work, shows a curve approaching more nearly to the ideal of a rise throughout the week.

The last section of the report records a short experiment with rest pauses, in which two of a team of three women operatives employed in the press room worked forty minutes, while one rested twenty minutes and then replaced one of the workers. Thus each operative was only actively employed for about thirty hours a week instead of forty-six. A considerable increase of output was obtained, the increase resulting more from the comparatively unskilled and less robust workers, who would naturally be more liable to fatigue, than from those whose output was high before the rest pauses were instituted. The experiment proved to the advantage both of employees and employers. The employers increased the output per machine by roughly fifty per cent; the number of accidents was sensibly reduced, and the employees were contented, declaring that they were less tired and in better health.

WORKMEN'S COMPENSATION AND DISPENSARIES

A conference was recently called in Rhode Island between a committee representing the State Board of Charities, representatives of insurance companies, and the superintendents of a number of dispensaries recently to discuss the charge that contracts or at least understandings had been entered into between insurance companies dealing in workmen's compensation and the management of certain dispensaries whereby injured workmen are treated gratis by the medical staff of the dispensaries, the insurance being collected by dispensaries to the detriment of physicians.

The point of view expressed by each member of the conference is varied and of great interest, as reported by the *Long Island Medical Journal*. The insurance companies maintained that their one care was to obtain the best form of treatment for their injured insured; that often the ordinary family physician was not available or was not versed in compensation requirements, or lacked the necessary training or the requisite office equipment. They denied that contracts had been entered into with dispensaries, but ventured the opinion that a well equipped dispensary offered treatment for an injured man that might make it worth while to establish a definite relationship. The superintendents of several large dispensaries acknowledged that they had regularly accepted compensation cases for treatment in their clinics. The objection on the part of physicians represented held that unjust discrimination is caused by working agreements between dispensaries and insurance companies.

In commenting on the matter, the *Journal* emphasizes the trend of modern institutional work to provide opportunities in a more generous spirit for all classes of society

and cautions the physician that he must "study how to keep in the van of progress at the same time that he guards himself from commercial imposition." They suggest that it might be worth while to abrogate entirely the arbitrary definition of what constitutes a charity patient and to accept all out-patient applicants on a graded fee schedule, while the dispensary physician receives a salary. Such a plan has been tried and it seems susceptible of adjustment until it may be made to meet the needs of the profession and public alike. There must be a readjustment of all three parties to meet the situation, and the suggestion of a graded pay clinic, carefully controlled, with an efficient investigative department to check up on the inevitable unworthy applicant, seems to offer a means to meet the just claims of all parties—patient, doctor, dispensary, and insurance company.

TREND OF WORKMEN'S COMPENSATION

An article contributed by Will J. French, in the November issue of the *Monthly Labor Review*, summarizes compensation history, past and present. The most important recent legislative development of workmen's compensation legislation is in extending the benefits of compensation acts to include vocational re-education and rehabilitation of men disabled in industry. Without waiting for the Federal Industrial Rehabilitation Act, a number of states have proceeded independently to provide re-education for injured workers. Some tendency is noted toward more compulsory and monopolistic state funds. This is, of course, resisted bitterly by stock and other private insurance carriers. The fact that child labor is excluded from compensation Mr. French regards as without reason, and thinks that all laws which are limited to extra-hazardous and hazardous occupations should be extended to all industrial occupations without regard to extent of hazard.

A STRONG BRIEF FOR VIVISECTION

Were it not for its unfortunate name, vivisection would have less need of explaining from time to time the necessity for its existence, according to the *Boston Transcript* in commenting on a series of lectures at Georgetown University, brought out under the editorship of Francis A. Tondorf, S.J., Ph.D. Vivisection may at one time have been the fulfillment of its name, but it has moved upwards into animal experimentation on which is based the whole fabric of modern medicine and surgery and has been a means towards the enormous improvement in the "expectation of life" of the whole civilized world.

At the Georgetown University of Medicine during the present year more than a dozen distinguished authorities of the country were invited to deliver lectures in vindication of vivisection. Among the speakers in the symposium were Simon Flexner, M.D., Sc.D., who detailed experiments with animals which directly benefited all classes of men; William H. Arthur, M.D., Col., U. S. A., on laboratories; George Tully Vaughan, M.D., on cerebral surgery and other difficult operations which have been rendered surgically safe; W. W. Keane, on modern antiseptic methods which have revolutionized abdominal surgery, eliminated lockjaw, and have reduced the death rate from compound fractures from 66 per cent to less than 1 per cent; and Maj. George B. Foster, M.D., Dr.P.H., who recounted the incontrovertible accomplishments of the Army Medical Corps. The whole present achievement and the best promise of the future may be claimed as a just result of utilizing the study of animals and bacteria by watchful investigators who have been interpreting their reactions for the benefit of the human race.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

AN ATLAS OF THE PRIMARY AND CUTANEOUS LESIONS OF ACQUIRED SYPHILIS IN THE MALE. By Charles F. White and W. Herbert Brown.¹

The opportunity afforded the authors of seeing some 19,000 cases of syphilis in hospitals during the war afforded them a clinical material from which the illustrations of this atlas were made. The illustrations throughout are of the highest order. The colored plates and stereoscopic reproductions of photographs share equally in the merits of the publication. The legends thereto attached and the scant but clear cut reading material are both excellent and highly descriptive. The print throughout and the general physical characters of the book are of the highest order. Plate IV in Part V is undoubtedly the best illustration which has thus far come to the attention of the reviewer. This Atlas will be highly appreciated by all specialists in syphilology.

J. S. EISENSTAEDT.

THE OKLAHOMA HEALTH SURVEY, MUSKOGEE.

By M. P. Howard, M. S., and Jules Schevitz, B. S., Under the Auspices of the Oklahoma Tuberculosis Association, Oklahoma City, Okla.²

The health survey of Muskogee is the second of a series of eight complete and intensive health surveys of urban conditions in Oklahoma undertaken by the Oklahoma Tuberculosis Association as a preliminary step in a state-wide health campaign.

In each case the community has been so organized as to bring the exact status of the district under the immediate supervision of a Central Health Survey Committee composed of local citizens. The data reported were gathered in 1918, and the impetus given to the interest in health conditions has persisted.

Muskogee stands incriminated as to her health machinery and administration on several counts. Specific death rates are high, notwithstanding a system under which the reports of diseases are so incomplete and meager as to make it impossible to calculate the true death rates or to determine the nature and prevalence of disease in the community. An attempt to calculate the infant mortality rate brought out the fact that only from 42 to 48 per cent of births are recorded. The model vital statistics law is not adhered to.

Quoting from the comment of the report on city budgets, "the city budgets for 1917 and 1918 show that the appropriations for health work was \$0.19 *per capita* in 1917 and \$0.14 *per capita* in 1918. This amount is unusually small, since the minimum appropriation for health work is estimated to be 50 cents *per capita*. The appropriation becomes even more insignificant when the items for which the money is spent are reviewed. A much smaller *per capita* appropriation is available for

preventing disease. The study brings out the fact that the expenditures for all the important municipal activities are many times as large as those for health work. More money is being spent for the care of the cemeteries than for the prevention of disease."

Water supplies, sewage disposal, housing—all call for scientific supervision.

The Oklahoma Association is to be commended for its enterprise, and the authors of this report for their methods and exhaustive analysis of the material collected.

STUDIES IN NEUROLOGY. By Henry Head, M. D., F. R. S., in conjunction with W. H. R. Rivers, M. D., F. R. S., Gordon Holmes, M. D., C. M. G., James Sherren, F. R. C. S., Theodore Thompson, M. D., and George Riddoch, M. D., Volumes I and II.³

These volumes consist mainly of a republication of a number of papers published by Head and his co-workers in *Brain* over a period of time extending from 1905 to 1918. No material change has been made in their arrangement. Each of these papers contain an account of the methods in testing sensation. These have been excised and a fresh chapter in which they are combined has been added. In introduction and an epilogue dealing with the common aims which underlie these various researches have been added. Finally, in the interest of clearing up some of the moot questions in neurological research, some of the most serious criticisms of their researches have been considered in an appendix.

The first volume is devoted to the peripheral nervous system. The profound studies here described resulted in a new conception of the physiology of sensation which has been widely accepted. Head, Rivers, and Sherren concluded that the sensory mechanism in the peripheral nerves consists of three systems: deep sensibility, protopathic sensibility, and epicritic sensibility.

The second volume is devoted to grouping of afferent impulses sensory disturbances from cerebral lesions and observations upon gross injuries of the spinal cord. After showing that afferent impulses which reach the central nervous system by way of the peripheral nerves undergo rearrangement within the spinal cord, they attempt to trace their course upward, indicating the relation of each set of impulses to the other. They complete their observations with exhaustive studies upon cerebral cortex and sensation.

The case reports are complete and the illustrations profuse. The volumes will be of great interest to neurologists, other clinicians, and physiologists. The collection of their valuable and separate studies into one accessible place is particularly timely, associated as it is with the reawakened interest in sensation due to the casualties of the late war.

1. John Bale, Sons & Danielson, Ltd., London, 1920.
2. Oklahoma Tuberculosis Assn., Oklahoma City, 1919.

3. Oxford University Press, New York, 1920.

THE OXFORD MEDICINE. By Various Authors. Edited by Henry A. Christian, A.M., M.D., Hersey professor of theory and practice of physic, Harvard University; physician-in-chief to the Peter Bent Brigham Hospital, Boston, Mass.; and Sir James Mackenzie, M.D., F.R.C.P., LL.D., F.R.S., consulting physician to the London Hospital and director of the Clinical Institute, St Andrews, Scotland. Volume II, diseases of bronchi, lungs, mediastinum, heart, arteries, and blood.⁴

This second volume lives up to the expectations produced by the first. The articles are all good, the presentation clear—at times brilliant. The bibliographies are extensive; the volume on the whole is a well rounded and authoritative treatise on diseases of the bronchi, lungs, mediastinum, circulation and blood. We know of none better.

MANUAL OF BACTERIOLOGY AND PATHOLOGY FOR NURSES. By Jay G. Roberts, Ph.G., M.D., Oskaloosa, Iowa. Third revised edition.⁵

An admirable little textbook covering both bacteriology and pathology in a concise manner. Its chief virtue is brevity, containing about all a student nurse should know about the subjects treated, without confusing her mind with a lot of unessential detail.

PLASTIC SURGERY OF THE FACE. Based on Selected Cases of War Injuries of the Face, Including Burns, with original illustrations. By H. D. Gillies. With chapter on the prosthetic problems of plastic surgery by Capt. W. Kelsey Fry, M.C., R.A.M.C.; and remarks on anesthesia by Capt. R. Wade, R.A.M.C.⁶

Those who were fortunate enough to hear H. D. Gillies present his paper before the Clinical Congress of the American College of Surgeons in New York in October, 1919, or who have followed his work will have anticipated the excellence of his book on plastic surgery of the face. To those who do not know of him a few remarks regarding his qualifications for writing such a book might be opportune. In 1915, while serving with the Red Cross in France, Dr. Gillies conceived the idea of devoting a hospital to the treatment of face wounds, and with this in view he was assigned a small ward in the Cambridge Hospital at Aldershot, England. Before very long more beds were needed, Aldershot could not be expanded and in 1917 a 320 bed hospital was established at Sidcup. By the end of the war the capacity had reached 530 beds, plus auxiliary units totaling several hundred beds more. In this hospital, with its thousands of admissions, Major Gillies worked, devising and perfecting operations to restore as nearly as possible to normal, functionally and cosmetically, the horrible battle wounds of the face. This experience, gained by innumerable painstaking endeavors and by prolonged post-operative observations, he has recorded clearly and concisely in this book.

The text is elaborately illustrated with diagrams and photographs which depict the various stages of operation and healing and the final results. The first chapter, on the Principles of Plastic Surgery, sets forth the fundamental essentials of plastic surgery. It tells what preliminary treatment is necessary, how to plan the repair, what tissues can be used to replace mucous membrane, skin, supporting tissue, how to determine whether sufficient blood supply be present, how much tension or torsion a flap can stand, where Thiersch, Wolfe or pedicle flaps are most efficient, etc. With the same painstaking care the repair of injuries to various parts of the face are described, Chapter 2 dealing with repair of the cheek, Chapter 3 with repair of the upper lip, Chapter 6 repair of

injuries to the nose, etc. Except perhaps in work on fractures, there is no subdivision of war surgery in which the principles learned can so readily and with so little change be transplanted to civil life as in the case of plastic face surgery. In the final pages of the book Gillies deals with this phase of the subject, indicating in brief where and how the methods described in the previous chapters are applicable in a civil community. A careful index enhances the value of the work as a reference book.

Gillies' Plastic Surgery of the Face rightfully deserves a place of pre-eminence among recent surgical works.

CREATIVE CHEMISTRY. Descriptive of Recent Achievements in the Chemical Industries. By Edwin E. Slosson, M. S., Ph. D., literary editor of *The Independent*, associate in Columbia School of Journalism. Author of "Great American Universities," "Major Prophets of Today," etc.⁷

The recent war, states Stieglitz in an introductory chapter to this volume, as never before in the history of the world, has brought all nations to a realization of the vital place which the science of chemistry holds in the development of the resources of a nation. This most important fact, it seems, is not fully appreciated by the general public. Its generous and intelligent support, however, is indispensable if the more recent achievements of industrial chemistry shall be preserved, and the hoped for results of further chemical research be obtained. The interest of the public must be awakened, and there probably is in this country no other scientist better equipped to accomplish this feat than Slosson, the author of this new volume. He brings home to his readers some of the great results of chemical activity and discusses some of those big problems which must continue to engage the attention of the chemists. The story of creative chemistry is told in a most captivating style. Chemical formulas, figures, and statistics, like the less palatable but essential ingredients of a powerful medicine, are well dissolved in a pleasant vehicle of fluent diction, tastefully flavored with cheerful criticism, and here and there even a quotation from poetry. But also in this unique and attractive disguise this remains a serious and truly scientific treatise with many references for collateral reading, a work easily perused and destined to achieve its purpose of arousing widespread interest in the science of chemistry.

THE LIFE AND WORK OF SIR JAGADIS C. BOSE, M. A., D. Sc., LL. D., F. R. S., C. I. E., C. S. I., emeritus professor, Presidency College Calcutta, director of the Bose Research Institute. By Patrick Geddes, late professor of botany (Univ. Coll., Dundee), St. Andrews University, and professor of sociology and civics, University of Bombay.⁸

Some books impress you by their mere title, and no matter how critical you would like to be after that you cannot free yourself from your first impression. To this type of books belongs the one before us. The book makes a splendid impression by its title, contents, and photographs. As one reads he finds the first impression to be correct. It is a biography of Professor Bose, an Indian scientist, but the author has sketched in the book the life of the people in India, the struggle of a man who in the midst of a primitive culture becomes interested in scientific research, and the workings of an institute of learning in the far East. The book removes one from European and American civilization and gives an insight to a primitive and a natural culture. It is refreshing and instructive.

Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 69)

HYGIENE AND SANITATION. By Seneca Egbert, A.M.,⁹ M.D., professor of hygiene, University of Pennsylvania.⁸

This is a revised edition of a useful textbook along conventional lines. Out of a total of 538 pages comprising the book, 31 are devoted to air, 82 to water, 47 to food, 31 to the examination of air, water and food, 50 to disinfection and quarantine, while only 15 are given over to industrial hygiene and occupational diseases. Professor Egbert does not discuss the administrative, social, economic, and educational phases of public health and the bibliography referred to in the footnotes is very limited, many important recent studies in the various fields not being mentioned.

The author is enthusiastic with regard to his chosen field. In the introductory chapter he makes a plea to the medical fraternity for a more active interest in sanitation on their part and musters several arguments for the support of his thesis, one of which is strikingly persuasive: "Health means ability to work and to earn good wages" and "good wages insure prompt and willing payment of the doctor's bills." The author is evidently a strong believer in the "economic interpretation of history."

E. H. L. C.

THE WOMAN OF THE STREETS. By Lee Alexander Stone, M.D., Major, M. C., U. S. R.¹⁰

The complex problem of prostitution has been discussed too often and too exhaustively to permit any writer to present in a small volume any entirely new information. However, it is possible to give known facts, which for various reasons customarily are suppressed, in such form that they bring home forcibly an opinion, which though at variance with common views, still is entirely feasible. This task has been ably performed by the author of this book. The question of prostitution so far has withstood all the multifarious attempts of a final solution. It can not be denied that the suggestions for a solution offered by Stone in this well written and easily readable volume are as acceptable as many propounded and then proved unsuccessful in the past. They at least impress the reader with their eminent sanity.

MASSAGE AND EXERCISES COMBINED. A Permanent Physical Culture Course for Men, Women and Children. By Albrecht Jensen.¹¹

The value of calisthenics is obvious. Its power to build up the human body has been most forcibly demonstrated in the army. Whether there is any special value in this or any other "new system" is rather doubtful. It reminds one of some of the complicated "stunts" some enthusiasts tried to introduce into the army. Calisthenics are now on a rational basis and it seems that the addition of a sort of pseud-massage only complicates an otherwise simple matter, without adding materially to its usefulness.

A MANUAL OF PATHOLOGY. By Guthrie McConnell, M.D.¹²

In a general way this is a satisfactory manual of pathology. The book is well arranged and the illustrations are quite good. A number of subjects are not very well treated, among these being the following:

The subject of focal infections; endothelioma; and the question of the etiology of poliomyelitis.

The impression is that the attempt is made to make the book too comprehensive by including bacteriology.

Number 2

PROLIFIC HEALTH LEGISLATION

THE legislatures of forty-three states are in regular session during this year. Only five states—Louisiana, Kentucky, Virginia, Mississippi, and Maryland—do not have regular sessions in the odd numbered years. There are indications that the year will be prolific in health and welfare legislation. The people of the states have had time to consider many of the weaknesses disclosed during the period of war stress and, although there will be apparently general approval of economy without strict regard to need, it is probable that many good measures will pass.

The field which is especially promising for legislation is that of child welfare. A number of official and unofficial commissions are reporting well rounded programs for the health and moral welfare of children. The subject of maternity care will also receive much attention, following the favorable action by the Congress of the United States. State health laws will be due for normal advance; research work will be given special impetus in the state universities; disabled civilians will be aided by legislation to meet the conditions of the Federal Act for the rehabilitation of cripples. Health center bills are being promoted in several states. Workmen's compensation, including more adequate medical care, will be considered throughout the country. The defeat by referendum of the anti-vaccination and anti-vivisection bills on the Pacific Coast, will doubtless serve as a warning to public health marauders. Limited practice bills providing for special boards for chiropractors, naturopaths, will doubtless be introduced in many states; but there are evidences, such as the defeat of the chiropractor bill in California, to encourage those who have been fighting to observe medical standards.

MODERN MEDICINE will at as early a date as practicable publish a complete and analytical review of health enactments during the sessions of 1920-21.

A SALLY AT PREVENTIVE MEDICINE

THE brilliant essayist, Mr. G. K. Chesterton, has been lecturing in the United States, and his wit has been emitting sparks. Among them was one which flew in the direction of the modern health movement. We do not doubt that his audience responded reprovingly when he ridiculed the idea that the doctor should be the health officer of the community. For doctors as doctors, the lecturer said, he had profound respect; but he would knock their heads off if they undertook to make themselves advisers of the community. The doctor was to be called upon extraordinary occasions to deal with abnormal situations. Suppose he were to precipitate himself into the audience and break his leg. A doctor would set the leg. He would be doing his work as a doctor, but the modern idea seemed to be that he was to take charge of unbroken legs, to say when they were to be used to walk, and when they were to be used to dance.

"Take a policeman. He is there to punish crime," Mr. Chesterton continued. "When you and I indulge in murder, he takes charge of us and deals with us according to law. But just imagine what you would say if told that the policeman was there to encourage virtue. What would happen if you and I were always followed by a policeman, and we heard his voice over our shoulder telling us when to do this and not to do that? I think we should soon begin to look upon it as rather a bore.

"As a matter of fact, precisely this sort of thing

is messing its way into our extremely muddled politics. In England they have created a Ministry of Health—God knows why! In English cities, its agents are endured with the incredible politeness that is characteristic of the English poor. In Edinburgh and other places, where Scotchmen live, they are kicked downstairs. In Ireland they are not allowed at all."

This sally at modern preventive medicine and public health measures may amuse but it does not save lives. Everyone acquainted with modern health movements knows that the physicians and the health workers do not interfere with the liberties of people except where the liberty of one may mean disaster to another. Health regulations attempt to give babies and children a chance against the ignorance and indifference of parents. They prevent disease carriers from endangering the welfare of others. They require those who maintain a nuisance inimical to health to clean up. They prevent dependents from preventable causes from remaining dependent.

Preventive measures are necessary in every community and nowhere are they carried to such extremes as the wit of Mr. Chesterton indicates. Inadequate as are the health measures of this country today, they are responsible for the saving of at least a million and a half of lives which would be lost if the rampant individualism lauded by Mr. Chesterton prevailed.

WILLIAM T. SEDGWICK DIES

NEWS has just been received of the sudden death of Prof. William T. Sedgwick of the Massachusetts Institute of Technology. Dr. Sedgwick has been for many years one of the most outstanding figures in the field of public health as an authority on biology and sanitation, as a Technology official, and as a teacher in numerous scientific branches. He has during the past twenty-five years exerted a formative influence on public opinion in such matters and has been an inspiration to many of the foremost health workers in the United States today.

Professor Sedgwick was born at West Hartford, Conn., in 1855, graduated from Sheffield Scientific School in 1877, and taught for five years at Johns Hopkins. He had long been recognized by his associates as a leader in his branch of science, and had served as president of the American Society of Naturalists, on the Advisory Board of the Hygienic Health Laboratory of the United States, as president of the American Health Association and the Society of American Bacteriologists. Since 1897, as curator of Lowell Institute, he had arranged the famous Lowell lectures. Two of his books were "Principles of

Sanitary Science and Public Health" and "The Human Mechanism." A résumé of his views on the present needs of medical education was published in the January issue of MODERN MEDICINE.

POPULAR NOTIONS REGARDING PSYCHOLOGY

THE University of Iowa is striving to make its science reach the people instead of merely serving the mission of academic discipline. In line with this aim is a recent investigation by Donald A. Laird, reported in the *Journal of Abnormal Psychology*, to ascertain how accurate are the ideas of the man of the street with reference to the cardinal conceptions of abnormal psychology. For the purpose of this investigation Laird culled from important texts on psychology the topics most emphasized as of practical value and incorporated them into a questionnaire that the average individual might comprehend.

A surprisingly high percentage of returns was secured and an unbiased sampling of cases revealed the vagueness of the popular mind on these subjects. Out of 100 replies, 72 frankly admitted they did not have any idea as to the cause of dreams, 59 thought dreams have occasional prophetic import, and none was in any way acquainted with the wish fulfilling aspect of the dream. On the subject of hypnosis, 64 did not place any belief in the validity of the phenomenon, while 13 frankly called it a fake. Of the 36 who believed in hypnosis, 14 ascribed it to some "unknown" power, while the others thought it uncanny. Only 19 thought the account given of a typical hypnotic case of multiple personality possible. On the question regarding the subconscious only 12 replied in the affirmative, and these had only a vague concept of the subconscious.

When the questionnaire passed to occult manifestations, however, the tendency was in the other direction; 58 believed that the spirits of deceased persons live and can communicate with us, and all but two of the 58 believed that only certain persons have the power of getting in touch with the spirits of the departed. None of the group had read about hypnosis or multiple personality. Compare this meager amount of knowledge as to the processes of mentation with what was actually forced upon their attention in the Sunday supplements about occult phenomena! Wherefore the author recommends as useful the fertile field of semi-popular articles dealing with the several phases of psychology that will catch the eye and the mind of the man on the street and build fuller, more accurate concepts of mental science to replace injurious current notions regarding spiritualism and telepathy.

S. P. M.

THE AMERICAN RED CROSS AND HEALTH*

BY E. A. PETERSON, M.D., DIRECTOR OF HEALTH SERVICE, AND W. H. BROWN, M.D., ASSOCIATE DIRECTOR OF HEALTH SERVICE, WASHINGTON, D. C.

THE origin and development of the Red Cross idea is one of the most striking by-products of war. Called into being to meet the emergencies of the battlefield, it has grown to be a living organ of personal mercy the world over. The mercy thus enthroned in the heart of man has not confined its efforts to the dramatic needs of war, but has extended its ministrations to the equally pressing needs of peace. So today we have Red Cross societies in forty-one countries, with an International League of Red Cross Societies maintaining a permanent organization at Geneva. These organizations all have the common ideal of translating mercy into universal service for humanity everywhere.

The American Red Cross Society was born in 1881. This organization traces its ancestry back to the work of Florence Nightingale in the Crimea and the practical sympathy of a Swiss gentleman, M. Henri Dunant, on the battlefield of Solferino. Out of their unselfish devotion came a conference at Geneva to consider the foundation of an international society for the succor of the wounded. As a result of this conference in 1864, twelve of the most enlightened nations of the world signed the "Treaty of Geneva for the Relief of Sick and Wounded Soldiers." Our country was not able to enter this humanitarian agreement at this time.

America in Organized Mercy

In this country the real precursor of the Red Cross was the United States Sanitary Commission. This was formed in 1861 with the motive of devising means of aiding the medical service of the army. An extra-governmental agency, it was at first not favorably regarded, though after some difficulties it was given recognition and

This picture depicts the homage of America's fighting men to American womanhood as mobilized for service in the World War by this organization. The face of the central figure is a composite of the features of one thousand Red Cross workers, officially selected for the purpose.

throughout the Civil War carried on health and relief work. At the close of the war, an attempt was made to form a permanent relief organization but, through lack of interest, this failed. In 1877 a message from the president of the International Red Cross to President Hays, urging the founding of an American Red Cross, was delivered by Miss Clara Barton, who had been active in nursing during the war. Finally, in 1882, through the energy and perseverance of Miss Barton, President Arthur signed the Geneva Treaty and it was confirmed by the Senate. This was the official recognition by our government of the principle of organized mercy.

Even after the adoption of the Red Cross system for the relief of the disasters of war, there was objection to perpetuating it on the ground that we had no wars and were not likely to have any. This seemingly unanswerable argument was met by pointing out the lack of any organized provision for meeting the constantly recurring disasters of peace, such as fire, floods, famine, and epidemic disease.

The further growth and development of the American Red Cross is an interesting story. Almost immediately it was called upon to perform service. Forest fires, floods, and famines occurred and relief had to be provided. Its first public health work came with the yellow fever epidemic of 1888 in Florida. A group of persons who had previously nursed yellow fever patients were gathered together under Red Cross auspices and sent to the places visited by this disease. Armenia was the next field for health work. In 1894, during one of the periodic disturbances between Moslems and Christians, a Red Cross expedition, after some difficulties, entered this Turkish province. Here it had to cope with four distinct epidemics:

*The sixth of a series of articles on national health organizations appearing in successive issues of MODERN MEDICINE.

typhoid, typhus, dysentery, and smallpox. Cuba, in 1898, was the scene of horrible conditions. The Red Cross went there, opened hospitals, distributed supplies, and did what it could do to alleviate the sufferings of the unfortunate inhabitants.

At last, the American Red Cross was finally and permanently incorporated in 1905. The President of the United States became its president and the War Department its auditor. In its charter it was officially designated "To continue and carry on a system of national and international relief in time of peace and to apply the same in mitigating the sufferings caused by pestilence, famine, fire, floods, and other great national calamities, and to devise and carry on measures for preventing the same."

The years following its incorporation were years of unconscious preparation of the organization for the duties and responsibilities of the World War. During this time, the Red Cross accumulated experience in the handling of national and international disasters of all kinds, whether wars, floods, fires, famines, earthquakes, cyclones, or epidemics. In this article we are only interested in those activities which have a direct bearing on health problems. From the Town and Country Nursing Service has developed one of the most striking as well as one of the most useful contributions of the Red Cross in the field of health—the Red Cross public health nurse. From a little group of courageous pioneers, they have grown to almost 1,200 trained young women fighting disease and promoting health in 850 American communities. Supporting, supplementing, and assisting the constituted health authorities, they are acknowledged to be one of the indispensable parts of modern health machinery.

Health education soon became one of the major activities of the Red Cross. The courses in home hygiene and care of the sick have furnished 168,709 women and girls with fundamentals that will materially assist the physicians of our country in their battle with disease. In addition, the courses in food selection have had a very direct bearing on health. The first aid work of the Red Cross has placed definite and useful facts about accidents and their prevention in the hands of 16,000 persons within the last twenty months, while Red Cross life saving courses have prepared 2,817 men and women to meet emergencies in and on the water. The activities of this period furnished the Red Cross with a broad experience in cooperation with official and voluntary agencies, the working methods evolved developed a technic of enlisting and training personnel and a popular appeal to the public both as a teacher and as an avenue of service.

Then came the World War. In common with every good American organization the Red Cross expanded to meet our country's need. With its traditions of service and its training in organization, it mobilized for war and enlisted both the interest and funds of millions of our people. The story of this service can not be recorded here. We should point out, however, that the war led the Red Cross more positively and extensively into the health field.

Extension in Health Field

At home, its chief health work was the sanitation of the extra-cantonment zones established by the army for making effective the sanitary work within the camps. In addition it furnished funds and personnel in its cooperation with the United States Public Health Service and the health officials in combating the influenza epidemic. Abroad, the record of the Red Cross is a long one. It operated in twenty-five foreign countries, doing everything from literally "practicing medicine" to sustaining a nation. With material relief and medical aid it served the civilian population as well as the military organization. It fed the malnourished children of France, fought typhus fever in Serbia, and promoted school hygiene in Italy. The whole of Europe and parts of Asia knew the symbol of the American Red Cross. All of these things were possible only because here at home this symbol appealed to the hearts and hands of the people of our country to a degree that made 22,000,000 of them become members of the organization, and 8,000,000 of them actively enlist for personal service.

The unit of Red Cross organization was a little band of people called a chapter. Three thousand of these, with seventeen thousand branches were scattered all over this country. For ease of administration these chapters and branches, were grouped into fourteen larger units called divisions; the divisions in turn were responsible to the Central Committee at National Headquarters in Washington. This was the machinery which was organized to reach millions of our population quickly and effectively in order that they might do their part towards meeting the needs of their government at war. Through this machinery the Red Cross taught its members how to serve freely for the common good.

Through this extension it became the most tremendous organized social force in the history of the world.

With the signing of the armistice a new situation confronted the Red Cross. There had been built up this enormous voluntary organization. By actual demonstration it had proved its ability to carry on an extensive system of relief and

health work. In doing this it had drawn upon hitherto untapped reservoirs of service for the common good in the shape of millions of volunteers. The great force called into play had proven one of the important factors in the successful supplying of the necessities of war.

Might it not also be of great value in meeting the problems of peace? Should the Red Cross junk this great organization and dissipate this spirit of public service drawn out by the emergency? The answer to these questions involved a grave responsibility. After careful study and mature deliberation it was decided that an effort would be made to conserve this great social force and direct it into channels where it promised to be of real service to our country.

The next problem was to select a field in which this kind of a force would be most useful. By reason of the past history, traditions, and experience of the American Red Cross one of the fields chosen was that of public health. Accordingly, it was planned to study carefully the health problems and health resources of our country in order to determine whether there were any unmet needs in public health which might properly be assumed by the Red Cross. This study was conducted with the full appreciation of the fact that in its last analysis the protection of the public health and prevention of disease is an official responsibility; further, that any activities of the Red Cross must lead toward the time

when the legally constituted health authorities shall be provided with adequate funds and sufficient public support to enable them to handle the whole health job without the assistance of voluntary health organizations.

In reaching a decision as to the direction the Red Cross should take in the field of health it was necessary to review the major public health problems which are occupying the time and attention of health workers of the country. It is neither necessary nor desirable to discuss these problems in detail in this article. For purposes of study

they were considered broadly in order to determine whether there could be found any common factor which might indicate a course of action. This broad classification of public health problems may be of general interest: (1) Control of communicable diseases; (2) detection and correction of physical defects; (3) prevention of disease; and (4) promotion of health and prolongation of life.

The control of communicable diseases continues to be one of the major activities of health workers. One needs to but run over the list of causes of death to bring vividly to mind the work that remains to be done in this field. This is true, notwithstanding the fact that science has accumulated knowledge of the cause, mode of transmis-

American Red Cross National Headquarters, Washington, D. C. It has been conceived as a National Headquarters comparable to Army Headquarters issuing to its division commanders orders which in turn were issued and carried out by the chapters and branches to a force of some twenty million members. Its membership constitutes a tremendous social force.

sion, and cure of many of these diseases. In addition, well trained health workers stand eager and willing to apply this knowledge. When these facts are considered, it seems almost incredible that communicable diseases should continue to account for 21 per cent of all reported deaths. The reason for this state of affairs is not to be found in the unsoundness of our scientific knowledge or the unwillingness of our health organizations, but is to be found in lack of proper education of our people in matters pertaining to health; for the testimony of our best health workers all agrees that it is not by legislation but by educa-

tion that the control of communicable diseases can be attained.

Health Inventory is Made

The detection and correction of physical defects is one of the newer but none the less important, of our health problems. Originally brought to light by the examination of our school children, we have had striking confirmation of its importance from the compulsory physical inventory of a special group of our population under the Selective Service Act. The figures and percentages of defects revealed by these examinations are only of passing interest, but the medical interpretation of them is of vital significance. Our best medical men have told us that a large percentage of these defects could have been easily corrected in childhood. All health workers are united in the desire to have this corrective work done, but only a small percentage of our school children are securing the proper inspection and instruction. Investigation shows no lack of knowledge of how this problem can be solved, but does show a lack of appreciation of its importance by enough of the citizens of our country to have it translated into the official machinery to accomplish it. This appreciation can be brought about only by education.

The prevention of disease is one of later activities of the health authorities. It has only been possible for us to focus our attention upon this subject since scientific investigation has furnished us with exact knowledge of the cause, mode of transmission, and method of diagnosis of the various types of disease. Upon this knowledge has been built up the administrative machinery for actually preventing disease. Laws have been passed, budgets furnished, and public support accorded that have enabled the official health machinery to function with great efficiency with reference to some diseases. This is strikingly illustrated in many parts of our country in the case of typhoid fever. On the other hand, with all of the essential facts at hand about such diseases as tuberculosis, smallpox, and venereal disease, the health official is not able to function to his highest efficiency because public opinion has not advanced to the point where sufficient powers and funds are provided for the adequate control of these diseases. The health authorities of this country can advance no more rapidly than public opinion will permit them.

The promotion of health and the prolongation of life constitute the latest among our health problems to receive proper recognition. Until very recently our activities in the health field have been largely defensive. Many of our best health departments were organized to meet an emergency, such as an epidemic. As the trained scien-

tific minds of our country studied this problem of disease they discovered that the physical state of the human body was of equal importance with the infecting organisms which were playing upon it. Consequently there has grown up a realization of the need for a positive ideal of health. This newer conception of the problem has already demonstrated its usefulness. It has been very well said that in our battle against disease we have always been on the defensive; it is time for us to take the offensive and hold it. The problem involved in bringing this about, demands a method of reaching our population effectively with scientific knowledge in a usable form and through a channel that can touch every part of our country.

Health Resources in Two Groups

In a review of the health resources of our country was necessary in order intelligently to judge where the Red Cross could best apply its public health efforts, we found two great groups of health facilities. The one provides service for the individual. It is made up of the practising physicians, trained nurses, and a widespread system of hospitals and clinics; the other provides service for the whole community, including all of the federal, state and local health departments and a group of voluntary health organizations. Our study of these two groups was not made from a critical point of view nor with the idea of assuming any of the functions of any of the individuals or organizations. It was made for the definite purpose of finding the ways in which the energy and resources of the Red Cross could be brought to bear so that it would assist all of these workers to function to their highest efficiency. This involved a knowledge of the extent to which the field of health was being covered by already established agencies.

The consideration of the medical, nursing, and hospital service is not particularly pertinent to this article, though we realize that no public health program is complete which does not provide some way to secure a wider distribution of the benefits of scientific medicine to a larger percentage of our population. The way in which this can be done is not apparent, but it is clear that every effort should be made to conserve the ideals and initiative of the medical profession.

A study of the organizations interested in community health protection was of particular interest. They divided themselves into two groups: the governmental or official agencies, and the non-official or voluntary agencies. The official health agencies have been compelled to limit their development in accordance with the authority and budgets granted to them by our federal, state, and

local governments. As a consequence we have the health work of our national government scattered through many departments, whose health functions are only incidental. On the other hand, the states have absolute power in health matters within their borders, a fact which has resulted in a great variety of forms of health administration. The point of peculiar interest in this connection is the limitations it has so frequently placed upon the trained health officials of the country in carrying their health programs in making it necessary for scientific knowledge to be translated into law, through the intelligence of the average voter. This means, for the efficient functioning of our official agencies, raising the health intelligence of a majority of our citizens.

Notwithstanding the limitations placed upon the official agencies there have grown up a considerable group of well organized, excellently conducted federal bureaus, state, and local health departments. These bureaus and departments are headed by the leaders in public health thought. Under them they have gathered together a great corps of technically trained health workers who are capable of giving adequate health protection to the territory under their jurisdiction. The reason that these official health agencies are not meeting all of the needs in the field of health is to be found neither in a lack of scientific knowledge nor in their willingness to serve. It is to be found in the lack of sufficient authority and adequate support from the public. If we want these agencies to function to their capacity, this means universal public information and public education in the fundamental needs for health protection. It is not to be supposed that this group of official workers has not and is not continuing to strive earnestly to accomplish this end; but their progress has been comparatively slow because of the common misjudgment by the public of the motives of a public official who asks for increased powers and budgets. Out of this condition of affairs has developed a group of supplementary health agencies which will be discussed in the following paragraphs.

The organization and development of voluntary

health agencies has been, in part, a consequence of the limitations placed upon the health official. Another equally important factor has been the impatience of the more intelligent members of our communities to await the slow process of translating the benefits of scientific medicine into law through vote of our citizens. Consequently they have formed into groups with the double purpose of helping to educate the public and at the same time demonstrate the need of the particular measure in which they are interested. Further, all of them worthy of the name are temporary organizations; for, if they are based upon sound principles, they will be ready to disappear as soon as proper provision can be made by the health official out of the public funds to furnish the service they have been rendering. On this basis have grown up the National Tuberculosis Association, American Child Hygiene Association, American Social Hygiene Association, National Mental Hygiene Association, American Red Cross, and many other national and local organizations. The work of these great groups of health workers has been an important factor in the progress which this country has made toward furnishing adequate health service to 100 per cent of our population.

It became perfectly evident from our survey of the health problems and resources of our country that there were a great many unmet needs in the field of health. The problem was to study and classify them in a way which would enable us to judge whether any of them were proper fields for Red Cross activity. Briefly stated, some of the unmet needs which are fundamental to the development of the public health movement were

This gives the view of the front of a one-room Red Cross Health Center, showing an information desk near the door, and, at the sides, display tables for public health literature.

found to be some means of: (1) Providing sufficient powers and adequate support for legally constituted health authorities; (2) instituting a broader education of the public to the necessity of a well rounded system of public health service; and (3) bringing about a union of the forces in the field of health.

The first two of these needs are evidently dependent upon the education of individuals in matters pertaining to health. Further, it is undoubtedly true that progress will be conditioned in time upon our ability to reach large numbers of our people readily and effectively. This can only be accomplished by a union of the forces in the field of health. The time has come when, if we are in earnest about our desire to build up adequate health machinery for our country, it is incumbent upon both the official and voluntary health agencies to form a union of such a character as will enable us to secure real concerted action in the solution of our major public health problems. This kind of a union does not involve the sacrifice of the identity, rights, or privileges of its individual members any more than it has involved such sacrifices in the union of our states. An examination of these unmet needs in the field of public health made it certain that any one or all of them were suitable lines of activity for the American Red Cross. It only remained for us to examine the qualifications of the society and try to fit it into the place where it could do the most good.

The American Red Cross seems to be peculiarly well qualified to help the public health movement at this time because: (1) It is a great national organization with traditions, ideals and experience in health service. (2) It has a large membership grouped into thousands of local units. (3) It has a form of organization that will enable it to co-operate freely with every operating agency in the field of public health.

These qualifications indicated that the Red Cross possessed resources for rendering unusual service in the field of public health if a suitable program could be devised and the proper relationships established with the agencies already working in the field. If the ideals and experience in service of the millions of members of this Society could be enlisted and directed into health channels, it would advance the cause of public health in a measure that cannot be estimated. This assumed an unusual significance when it was found that the most pressing needs of the health movement were in the field of health education, a field for which the Red Cross is peculiarly fitted. Here, then, was found a basis for a health program which fitted the experience of great national

organization and at the same time promised to keep alive and active, for the public good, that wonderful spirit of unselfish service drawn out in the Red Cross by the emergency of war.

Great Responsibility Involved

The building of a Red Cross health program involved great responsibilities. To guard jealously against infringing upon the duties and functions of the constituted health authorities or other voluntary health agencies, at the same time to safeguard and conserve the best of our own organization constituted a difficult task. Mistakes have been made and misunderstandings have arisen, but none of them are insuperable. For the Red Cross reiterates its statement that it does not propose to swerve from its purpose of having all of its activities point toward the day when they shall be assumed entirely by proper authorities.

The Red Cross health program will follow two main lines of activity, health education and demonstration. These activities will be administered through the Department of Nursing and the newly established Department of Health Service.

The Department of Nursing has already made great advances in its health work through its public health nurses and its classes in home hygiene and care of the sick and food selection. This work is well known and well coordinated with the official health agencies. This is shown by the fact that the Red Cross has working agreements with twenty-six states whereby it shares the expenses of the placement and supervision of public health nurses. It is proposed to extend the nursing program and to continue actively to support the efforts to enroll and train sufficient nurses to meet the demands.

The Department of Health Service has been charged with the responsibility of carrying out the general health program. In this department has been grouped some of the older health activities—First Aid and Medical Social Service. It is proposed to continue and extend these activities as the circumstances warrant; but the main responsibility of the Health Service Department was to find a vehicle that would enable the Red Cross to function effectively in the general health field. Evidently this vehicle, if it was to fit the Red Cross, must utilize local organization; provide some means of cooperating with the constituted health authorities and with other voluntary organizations; and, finally, it must look toward the education of the people. The answer to the requirements has been found in the Health Center. It makes possible the local application of local resources; it permits each organization to work with the other without losing its identity;

and it provides a channel for the communication of authoritative health information to a large number of people.

The Red Cross does not claim to have invented the Health Center idea. For many years, it has been going through a definite period of evolution. It was originally conceived by public health workers in response to a universal need for some improved method of securing the more general application of the scientific knowledge of disease to individual cases. It is more than a mere coincidence that we find some form of effort developing under the name of Health Center, in England, France, Belgium, Wales, Australia, Canada, and Cuba, as well as in many parts of our own country. This can only mean that we are dealing with an idea of unusual value. It is not surprising, therefore, that a study of history of the health center idea brings out the fact that the term Health Center has come to be applied to many different kinds of efforts. We find it used as a name for child welfare

stations, tuberculosis dispensaries, venereal disease clinics, out-patient departments of hospitals, settlement houses, and substations of local health departments. A careful analysis of the origin and functions of these various activities working under this name yielded some interesting facts. It showed that in most institutions called health centers considerable clinical work is performed; in a comparatively small number, except those for children, little emphasis is placed on prevention; a few have brought together all of the agencies working in a given field; scarcely any of them have used the idea as a means of general health information and education. All of them have fallen short of their greatest usefulness because they lacked the social machinery to reach effectively a large percentage of the population.

As a result of this analysis, the Red Cross realized that by reason of the form and character of its organization, it was peculiarly fitted to supply the social machinery which would make the health center a powerful weapon in the hands of the public health workers. It has found in the health center an institution which can be locally operated with a minimum of outside direction. It

has found in it an activity that would enlist the interest of local Red Cross Chapters and could be carried by them in cooperation with local organizations, including the health department. It has found in the health center a means of personally delivering to people authoritative information regarding hygiene and sanitation. For these reasons the establishment and promotion of health centers has been made the chief project of the Health Service Department. On the basis of the experience and character of the Red Cross organization there has been planned a type of

View of the rear of a one-room Red Cross Health Center, showing a temporary exhibit on Child Welfare.

health center which includes the older conceptions of this idea, but emphasizes the modern idea of health education plus cooperation of all the health agencies working in a given field.

In its most elementary form the American Red Cross Health Center is an educational, informational institution. A carefully worked out illustrated pamphlet has been prepared giving local chapters detailed instructions as to how the Health Center is to be conducted in a way that it will meet local needs. These instructions are supplemented by the supervision of the trained health service directors placed at every Division headquarters. Through this official, proper relationships of this Red Cross activity will be established with the official health organizations. With this machinery the Health Center becomes really a clearing house for health resources. It brings to the community the wisdom and assistance of the great public and private health organizations; on the other hand, it does not fail to make full use of all local health assets.

In the establishment of these health centers the Red Cross invites the participation of every operating health agency in the field. One of the

MENTALLY DEFECTIVE CHILDREN*

BY A. LEVINSON, CHICAGO

IT SEEMS that the more civilized the world becomes the more idiotic it becomes. The world can boast now of more mental defectives than it could centuries ago, though it is possible this is because our advanced knowledge of the human mind makes easier the detection of mental deficiency. This, however, does not lessen the gravity of the fact that at the present time a high ratio both of children and adults are mentally below par. The questions that naturally present themselves to anyone who is interested in the subject are, (1) how to detect mental deficiency, and (2) what is the best way to treat mental deficiency in order to do the most good for the person affected and for society at large.

Many articles and books have been written on methods of detecting mental deficiency in adults and in children of school age. Very few authors, however, have laid sufficient stress on the detection of mental deficiency in infancy and pre-school age. Most children have their mentality standardized by the school teacher. Very few children are rated mentally before that period. As a matter of fact, the status of a child's mentality should be recognized much earlier than at the school period. It is unfortunate that to this day no standards of mentality have been worked out for infants; but even the common sense standards, such as the period when a child normally responds to light, begins to crawl, to stand, and to speak, provide adequate data on which a child may be regarded as belonging to one class or another. The human race has learned by experience that at the age of five or six months the child begins to sit up; that at the age of twelve or fourteen months the child begins to walk; that at the age of twelve to fifteen months the child begins to talk. Any child that does not conform to this standard may be considered as not normal.

It is, of course, necessary to make the time limit for mental activity quite flexible. The fact that a child cannot repeat all the words he hears

Altruistic motives demand for the feeble-minded an education and environment that will lead them into productive and useful lives. Society, however, must be protected against deterioration through them.

Improved methods for their detection and care will evolve out of present tendencies to recognize both physiological and psychological factors entering into the causation of mental and nervous disorders.

The possibility that even in infancy the signs of inadequacy are patent to trained observers makes feasible the registration of all defectives and a follow-up of those showing asocial tendencies which would afford both prevention and correction.

at the age of fifteen months does not suffice to put it in a class of mental defectives. It is the general intelligence of a child that counts, and not a single trait.

Parents should be the best judges of the mentality of their children. They are, however, either ignorant of what the child should be able to do or they are swept away by their parental love into hopes of a normal development even though delayed.

The question of mental tests for older children is important. As pointed out in another article of this series, observation over a long period needs to be made before a child is classed as a mental defective. Accepted intelligence tests are inaccurate, for what might be an easy question for a child with mechanical ability may be hard for another child equally intelligent, but not mechanically inclined. The worker should, therefore, realize his or her responsibility in the matter of applying intelligence tests.

The treatment of mental defectives must necessarily vary with the degree of mental deficiency, the etiology of the defect—if causes can be ascertained—and with the economic means of the parents. There are certain principles, however, that apply to all mental defectives, among which the following may be considered most important: (1) Recording of each case; (2) provision of epileptic colonies; (3) the organization of juvenile psychopathic clinics and hospitals; and (4) special schools or at least rooms for mental defectives.

If every mental defective were kept track of by health or police authorities and the behavior of these defectives watched as they grow older, many crimes would be prevented. Furthermore, by this means many crimes could be traced to those who committed them. If during infancy all children were rated as to their mentality, some of them who under present conditions are doomed to a life of idiocy could possibly be saved. I am referring in particular to the mental defective traceable to hereditary lues.

Society is slow to recognize the necessity of

*The tenth of a series of articles dealing with medicosociologic problems in the field of pediatrics prepared for the pages of MODERN MEDICINE by Dr. Levinson.

epileptic colonies, of juvenile psychopathic clinics, and of juvenile psychopathic hospitals. Had there been more epileptic colonies where life could be made comfortable to these unfortunate creatures, the need would have been much less for the provision of jails.

Emotionalized Estimates Unsafe

As yet we have no method of treating birth injuries due to cerebral hemorrhage, but in all such cases the earlier the recognition of delayed mental and physical development due to birth injury, the more it is possible to do in a palliative manner for that particular child. Physicians and social workers would do great service to the community if they would follow the newborn baby not only as to the gain or loss in weight and as to the number of stools, but also as to the progressive development of the child.

Whether the belief is accepted or not that most criminals are insane, it must be conceded that many crimes have as their background a history of epilepsy, the incidence of lues, or a preceding disease of the nervous system. Juvenile psychopathic clinics or hospitals where the maladies could be studied in conjunction with the social histories would be of great value.

Children who are very much behind the rest of the pupils in their class should not be kept in the regular class rooms. It disturbs the normal pupils, holds them back in their work, and gives them a chance to amuse themselves at the expense of the mental defectives. Every city and town should have teaching provisions for mentally defective children either in special schools or in special rooms at the regular schools. Those responsible for the care of such children need to be extremely interested in the work, even more so than ordinary teachers; unless the teachers are specially adapted to their extraordinary tasks, the teaching of the mental defective has no value whatever.

Nervous and Irritable Children

A discussion of mentally abnormal children in their relation to society must include the large class of children who can be classified as mentally defective, but who are nervous and irritable. Many children who seem to be in good physical condition sleep badly, do not eat well, are irritable and nervous. Excluding in these children the organic diseases—such as syphilis, meningitis, brain tumor, or brain abscess—as causes of nervous instability, there remains a large group of irritable and nervous children in whom no organic cause can be found but whose cases cannot remain unstudied. Often the cause can be eradicated and the child returned to normal. At times

the fault can be traced to such conditions as decayed teeth, enlarged tonsils and adenoids obstructing the breathing, or to some other low grade infection. At other times, however, the fault may lie in the mother or the grandmother; in the irregularity of life of the family, or in the over-education of the child. The physician, the nurse, or social worker may often render great service both to the individual and the community at large by the close observation of nervous and irritable children with a view to remedying the trouble.

RICHARD M. OLIN, M.D.

Under the incumbency of Dr. Richard M. Olin as Commissioner of Health, health work in Michigan has assumed an efficient activity which reaches all parts of the state. Special effort is being made to pass legislation to replace the present sixteen hundred township

health officers by full time health officers in every county of the state. "Give the rural child the same chances as the child of the Ghetto," said Dr. Olin in a recent bulletin.

The increased use of the state laboratories in Michigan serve as a barometer to indicate the people's interest and awakening to public health needs. When the laboratory budget was made out in 1918, about one thousand tests were being run monthly in the

state laboratories. In 1920 more than 120,000 specimens passed through the state laboratory at Lansing. These diagnoses covered everything from anthrax examinations to Widal reactions for typhoid, but the greater amount of work has centered around tests for diphtheria, syphilis, tuberculosis, and water analyses.

HEALTH PROGRESS IN ONTARIO

Three principal objectives have been before the health workers in Ontario for the past ten years, according to J. W. S. McCullough, in the July issue of the *Public Health Journal*: (1) the consolidation of the public health laws; (2) the lessening of the scourge of tuberculosis; and (3) the improvement of methods of administration. As a direct result of this concentration of efforts, Dr. McCullough reports progress in the past ten years as having curtailed the pernicious practice of changing the health officer every year, of paying more adequate salaries, and of providing a much larger percentage of full time men. Facilities for the intelligent handling of the tuberculosis problem have been greatly improved, laboratory service has been extended, the distribution of biological products promoted, and an active campaign against venereal diseases inaugurated. Notable advances have been made in the field of industrial hygiene. As a final index of awakened interest in health matters, Dr. McCullough mentions that, while health funds available in 1910 amounted to \$50,000, for the present year these appropriations amount to \$530,000.

SOME NOTES ON FOOD THERAPY

NEWBURGH,¹ from the University of Michigan at Ann Arbor, throws a new angle on the much disputed question as to fat and its use in the treatment of diabetes. The time is well remembered when diabetic patients were allowed all the cream, oil, or fresh butter wanted. The importance of restricting fats in the diabetic dietary has been recently emphasized, especially in this country, by Allen and Joslin.

However, it has been fully recognized that the low caloric diet and the under-nutrition that went with the new scheme of things were not completely satisfactory in the long run for many diabetic patients. Newburgh has treated seventy-three patients with a diet consisting of high fat, low protein, and low carbohydrates—a diet that on the face of it would seem to be definitely contraindicated in most cases of diabetes. Certainly the only tests of value in interpreting anything of this sort are the results. The results as given by Newburgh are, to say the least, interesting. We feel that he has opened up for investigation again an old angle, but that it will require much more intensive investigation before a final opinion can be expressed.

Compare with Newburgh's statement a recent article of Joslin's² on the prevention of diabetes. In this article the point of view is taken that the most important element in the cause of diabetes is obesity, and consequently the most important factor in the prevention of diabetes is the elimination of obesity. Joslin's statistics of one thousand of his own cases are remarkable. There is, however, no comparison made between the obese diabetic and the thin diabetic in regard to the severity, relative fatality, or

length of life. It is true from Joslin's statistics that obesity and diabetes run hand in hand in a large number of cases but that is as much as Joslin's statistics prove. Perhaps obesity is a defense phenomenon for diabetes.

While on the subject of diet, attention should be called to the contribution of Mosenthal,³ who studied a series of hypertension cases with the object of showing the effect of protein diet on the blood pressure. We know how frequently we tell our patients with high blood pressure to refrain from eating meats. We are rather glad to see that Mosenthal was unable to prove any definite relationship in his series of cases.

EDITOR.

THE OCULO-CARDIAC REFLEX

DURING the last few years much attention has been paid to the sympathetic nervous system. The work of Cannon and of Crile in this country and of Head and Brown in England has shown the clinical importance of the sympathetic nervous system. A recent contribution to this subject is concerned with the oculo-cardiac reflex, which consists of a change in heart rate on closure of the eyes. It has been found by a number of investigators^{1, 2, 3, 4} that under normal conditions closure of one or both eyes results in a bradycardia, but that in a state of shock this reflex is abolished. This state is termed "atony" of the centers. When the reflex is exaggerated, the condition is spoken of as hypervagotonia.

It is impossible at present to state how great may be

the importance of this particular reflex in clinical medicine. Results cannot fail to accrue, however, from the impetus given recently to the study of the sympathetic nervous system.

EXPERIMENTAL CHOLECYSTITIS

AN ARTICLE by Mann* affords an interesting field for speculation and may open the way to much interesting work.

Mann has produced an acute cholecystitis in dogs by the intravenous injection of Dakin's solution. The toxic effect of the solution, due primarily to the chlorin, is practically confined to the gall bladder, in comparison the other organs being but slightly affected. The resultant reaction comes on almost immediately and lasts for many months. The condition is not the result of an intravascular action of the chemicals because the results are the same if the cystic duct is ligated. The specific reaction seems to be on the blood vessels of the liver and most marked on the surface of the gallbladder on account of its greater vascularity. It may be concluded that a specific chemical cholecystitis is produced.

Although much work has been done on the gallbladder, we are still at a loss to explain the manner in which most of the pathological manifestations occur. It may be that further studies will disclose a method of causing a combined chemical and bacteriological cholecystitis presenting pathological pictures resembling those found in human beings. With available means of producing a specific chemical cholecystitis we may be a step nearer in reaching the solution of cholelithiasis, perhaps renal lithiasis as well. Mann's findings may be a very important clue in the effort to unravel the gallbladder mystery.

R. B. B.

PROTECTIVE VALUE OF PNEUMOCOCCUS VACCINE

WADSWORTH¹ has demonstrated that protection against *Pneumococcus* infection was obtained in mice and rabbits when large doses of *Pneumococcus* vaccine were used. The degree of protection obtained, however, was not great, considering the quantities of vaccine used to vaccinate the animals. The protection was restricted quite closely to the same type of *Pneumococcus* as that to which the vaccine belonged. The dose of vaccine used averaged about six billion organisms. In some animals only one injection was given; in some six, weekly doses, were given.

The important point to be emphasized, it seems to us, is the fact that even these huge doses of vaccine are but slight protection to these small animals. The size of the dose used is about the same as the doses of *Pneumococcus* and mixed vaccines which are on the market and are recommended as protective doses to human beings. If a dose comparable to those given to these small animals were given to human beings, it would be of a size out of all proportion to doses of vaccine which we are accustomed to use in other instances. The reaction in humans given a six billion dose of *Pneumococcus* is at times found quite severe. If this amount were multiplied by fifty or one hundred, to make it comparable to the amounts used experimentally by Wadsworth, it would be an overwhelming dose.

*Mann, F. C.: The Production by Chemical Means of a Specific Cholecystitis, *Ann. Surg.*, 1921, lxxiii, No. 1, p. 54.

1. Wadsworth, Augustus B.: The Protective Value of *Pneumococcus* Vaccination in Mice and Rabbits, *J. Immunol.*, 1920, v, p. 429.

The investigation of Wadsworth, therefore, bears out what seems to be the present clinical opinion, that the *Pneumococcus* vaccines which are available at present are worthless as prophylactics against pneumonia in human beings.

W. T.

SALVARSAN AND WASSERMANN-FAST SYPHILIS

THERE are two recent articles in literature which are specially important. One deals with cases of syphilis in which, despite very active treatment, the blood Wassermann test remains positive (Wassermann-fast syphilis). The other deals with the appearance of 1, 2, and even 3 plus blood Wassermann reactions in a series of non-syphilitic dermatological cases with negative Wassermann tests when repeated intravenous injections of salvarsan were given.

It is well known that a considerable percentage of syphilitic infections, especially old or latent cases, continue to show a strongly positive Wassermann reaction even after years of treatment with salvarsan and deep injections of mercury. Wile,¹ using a cholesterolized antigen in the Wassermann reaction, has reported that practically no cases of tabes or long standing, latent syphilis, become Wassermann negative with treatment. These extreme results are open to the criticism that cholesterolized antigen was used. The work reported by Busman and Stokes² is not open to this criticism, as in their tests a Noguchi antigen was used. Universal experience has also shown the correctness of the findings that Wassermann-fast cases of syphilis are not uncommon.

The question which naturally presents itself is: To what extent is the degree of control of a syphilitic infection indicated by the Wassermann reaction, and to what extent is salvarsan therapy indicated by this test?

This problem is being weighed in the balance at present and will only be answered after much painstaking work has been done.

It has occurred to Strickler³ that possibly the intravenous injections of salvarsan may itself produce some effect on the Wassermann reaction. He has put this idea to the experimental test and has found in a series of non-syphilitic dermatological cases, with negative Wassermann tests, that after repeated injections of salvarsan, the Wassermann reaction changes from negative to 1, 2, or 3 plus, in most of the cases. The number of salvarsan treatments varied from four to thirteen; 66 per cent gave two plus, or more, positive reactions. The number of injections of salvarsan necessary to produce a positive reaction varied from one to seven.

At least one important subject has had light thrown upon it by this investigation, and that is the question of the provocative salvarsan injections. Less and less confidence is being placed by all workers in the importance of a provocative salvarsan injection. The results of Strickler have shown the reasons why this empirical lack of confidence in the salvarsan test has developed.

The important phases of the subject to which we wish to call attention in reviewing these investigations are the relationship of the Wassermann test to Wassermann-fast syphilis; the value of the Wassermann test in following a

case of syphilis so far as indications for further treatment are concerned; and the doubt which is cast upon the value of a provocative salvarsan injection in cases of suspected syphilis.

W. T.

FILTRABLE VIRUS AND INFLUENZA

HALL¹ has injected intravenously and subcutaneously into animals filtrates from sputum of influenza cases, that have passed through Berkefeld or Mandler filters. In these animals there developed pulmonary lesions which were considered characteristic of those found in human cases of influenza. The filtrates injected were bacteriologically sterile, in the usual sense of the word.

This investigation is confirmatory of the results previously published by Olitsky and Gates.² These investigators injected the same type of material into rabbits by means of the bronchial route with the same results.

These two investigations, taken together, add considerable experimental evidence to the opinion which has been developing among clinicians, that epidemic influenza, or "flu," is not due to *Bacillus influenzae*, *Pneumococcus*, or *Streptococcus*, but is due to filtrable virus. Further investigations in this field are of extreme importance.

SURGICAL COLLAPSE OF THE APEX IN PULMONARY TUBERCULOSIS

SURGICAL collapse of the apex as a cure for advanced pulmonary tuberculosis has interested foreign surgeons, chiefly German,^{3,4} for a number of years. It has also recently been tried in this country, and by comparatively few men.^{5,6} The principle is the old one of organ rest, first conceived by Carson. When there are no adhesions between the lung and the pleura, artificial pneumothorax produces complete organ rest, and this procedure has come into a very definite field of usefulness for a particular group of pulmonary cases. If, however, in cases of this group, the lung cannot be collapsed by the introduction of air, the case goes on to the hopelessly tuberculous, with, of course, the hopeless prognosis. It is these cases, otherwise incurable, in which extra pleural collapse of the chest wall has been tried.

Sauerbruch⁷ reported the following results from extra pleural collapse: Of 41 patients, 8 were cured, 7 much improved, 13 improved, 3 remained unchanged, 4 became worse, and 6 died. A later tabulation of 122 cases showed 24 cured, 30 considerably improved, 32 improved, 4 unchanged or worse. Friedrich⁸ reported 28 cases with 19 recoveries.

All of these cases, it is to be remembered, were otherwise of hopeless prognosis.

Indications for the operation have been given as follows: (1) When the patient would die without surgical interference; (2) when the lesion is one sided and extensive, slight infection of the opposite lung and early tuberculosis involvement of the larynx not excluding the patient from operation; and (3) when, because of extensive pleural adhesions, artificial pneumothorax is impos-

sible. Most of the cases have had unsuccessful pneumothorax therapy for varying lengths of time.

Contra-indications are: (1) When considerable portions of the lung show caseous pneumonic infiltration; (2) the presence of ulcerous intestinal tuberculosis; (3) the presence of recent foci in the lower lobe of the other lung, or of old foci in the region of the hilum of the other lung; or (4) advanced debility.

The surgical procedures have been as follows:

(1) Resection of the first rib in front; also resection of a portion of the clavicle. This has been rather difficult and has been given up.

(2) Resection of the phrenic nerve at the neck to induce permanent paralysis of the diaphragm on the diseased side.

(3) Tuffier's operation "Apicolysis," with insertion of a plomb. This consists in resection of a short piece of the second and third ribs in the pre-axillary line, division of the posterior periosteal envelope of the rib, and collapsing the apex of the lung by separating the parietal plus adherent visceral pleura from the intra-thoracic fascia. The resulting free space is then filled up with fat or paraffin.

(4) The method of Sauerbruch is most widely used. It consists in resecting from the back portions of the first to the eleventh ribs, under local anesthesia. An incision is made about two inches from the spines of the vertebrae, extending from the first to the eleventh ribs. This is carried through the muscles and about two inches of each rib exposed, the field being well infiltrated and the intercostal nerves well blocked. Portions of each rib are then denuded of periosteum and resected. Great care is used not to puncture the pleura. About two inches of the first rib are resected, and the amount of rib resected increases from above downward, so that probably four inches of the last rib are taken away. This generally is sufficient to produce complete collapse.

(5) Wilms has modified the above procedure with the additional resection from the front of the first, second, third, and sometimes fourth ribs at the costochondral junction.

(6) Shivers⁹ advocates cutting the tendons of the pectoralis major and minor. After finishing the posterior resection the severed tendons are grasped from behind, pulled under the scapula, and attached to the cut muscles on the vertebral side of the wound. This, he thinks, will produce such complete collapse that anterior resection will seldom, if ever, be needed.

The chest wall must be retained in collapse by a snugly fitting bandage plus adhesive fixed to the sternum and vertebrae.

Shivers states that his primary mortality is 25 per cent, but all patients who live to get out of the hospital do remarkably well. Of twenty operations, only one patient succumbed to tuberculosis after recovering from operation.

HARRY C. SALTZSTEIN.

Many authorities have emphasized on various grounds the importance of play, but discussion passed to a firmer basis after the important work of Groos on the play of animals, for he shows that play was no mere safety valve for superabundant energy and spirits, no mere relaxation, no mere recapitulation, but that it was a joyous apprenticeship to the business of life, a time for replacing instinctive predispositions by learning from experience, a time of elbow room for variations, a time for experimenting before criticisms prune, before casualties induce caution, and before hard work brings on "life-harming heaviness."—Thomson.

PROGRESS IN PEDIATRICS—COLLECTIVE ABSTRACT*

SOME interesting contributions have been made during the year to the study of infectious diseases. McCulloch¹ studied the heart in diphtheria by means of the electrocardiograph. He found that in cases in which the effect on the heart is so profound as to interfere with the cardiac mechanism, the outcome is fatal. He believes that patients whose heart muscles alone are involved depend for their recovery largely on the ability to preserve a cardiac reserve sufficient for their needs. The moment this reserve is used up cardiac failure results. The author believes also that the occurrence of myocarditis following diphtheria is largely beyond our control, although the outcome is determined at least in some cases by the protection the heart receives during the course of the disease and during convalescence. The conclusions of this author are interesting because of the practice of many physicians in giving digitalis in cases of myocarditis following diphtheria. The work reported shows conclusively that there is no place for digitalis in that class of cases.

Immunity in Diphtheria

The Shick test and toxin antitoxin immunization is still a fruitful topic. Blum² tested 1,076 children for a period of five years. He found that the younger members of a family gave the same reaction as the older members. Where variations did occur, the younger members gave a positive and the older a negative reaction. In a series of cases in which he gave toxin antitoxin the immunity persisted for at least one or two months. Blum, therefore, believes that it is possible to render an institution free from diphtheria by toxin antitoxin.

Gorter, Bokkel, and Huinnink³ found that the Shick test became negative in more than 50 per cent of cases in which it was positive at the outset. They, therefore, believe that toxin antitoxin is a useful method in child caring institutions.

The question of diphtheria carriers has not been settled as yet. No matter what is being done for these children, they harbor the diphtheria bacilli in their throats. Of late tonsillectomy has been advised by a number of authors. Detling⁴ reports nine cases of diphtheria carriers in which he performed a tonsillectomy or adenoidectomy and was successful in clearing the throat of diphtheria bacilli. While he admits that no treatment has as yet proved successful in all cases, he believes that the removal of tonsils and adenoids gives the best results.

No Specific for Scarlet Fever

No startling work has been done this year on scarlet fever. A number of cases have been reported, but nothing unusual has been accomplished. It is interesting to note how every once in a while somebody discovers a new treatment for scarlet fever. This time it is salicylate of soda that is specific. Ramond⁵ claims that scarlet fever is amenable to salicylate treatment and it should be tried in all cases unless the patient has an idiosyncrasy against it. He believes that results are almost immediate; the

temperature falls, the pulse becomes slower, and diuresis follows. It is unfortunate that the author does not seem to know that salicylate of soda has been used in scarlet fever long before he discovered it. One who is familiar with the history of scarlet well knows that there is hardly a drug in the pharmacopeia that has not been tried for the treatment of this disease. There is very little hope, however, of finding any specific cure for the disease until the causative factor is determined.

Results in Pertussis

The work done this year on whooping cough is quite interesting. No less a pharmacologist than David Macht claims that benzyl benzoate not only relieves the whoop considerably but shortens the disease. So far, the only corroborative evidence outside of the author's own work was brought forth by McMurray,⁶ who claims that he obtained satisfactory and immediate results. In his cases the drug was given in doses varying from five to thirty drops and he claims to have seen a favorable effect within forty-eight hours, having observed no unsatisfactory results from it. It will be interesting to hear from other physicians how this remedy worked out in other hands. The reviewer has not seen any exceptional results from benzyl benzoate and was annoyed by the complicating nausea and vomiting that resulted from it. The discoverer of benzyl benzoate, however, is a man of exceptional ability, and judgment must, therefore, be withheld.

A new sign has been described for mumps. Cowie⁷ has found that the orifice of Steno's duct on the affected side presents a reddened spot measuring from 1 to 2 mm. in diameter. The duct is edematous and, as a whole, is pale, thus accentuating the central red spot. The duct sign was present in 96 per cent of the cases reported. This sign is interesting and awaits the corroboration of other authors.

The question of recurrent measles has been taken up by Salzmänn,⁸ who believes that a second attack is possible, an interesting idea because of the difficulty it presents in the diagnosis of rashes.

Every once in a while some author discovers that the Wassermann reaction is positive in a certain disease, overlooking the possibility that the reaction may be a mere coincidence in that particular case. Practically every disease has been ascribed to syphilis because the Wassermann was found positive in a few cases. This time it is reported that scarlet fever and measles were found to give a positive Wassermann in a few cases. Laederich and Bory⁹ found a positive Wassermann in sixteen cases of scarlet out of a total of twenty and a positive Wassermann in ten cases of measles out of a total of thirteen. They, therefore, conclude that with a sensitive antigen the Wassermann test is always positive in the first few of scarlet, and then tends to become negative, a finding that is true to a lesser degree in measles.

The Virus of Encephalitis

Interesting work has been done on encephalitis. Loewe, Hirshfield and Strauss¹⁰ obtained filtrable virus from the

nasopharyngeal mucous membrane of fatal cases of epidemic encephalitis. Later, they¹¹ found that filtrates of nasopharyngeal mucous membranes from epidemics of encephalitis produced corresponding lesions when injected intracranially into rabbits. It is to be hoped that the virus of encephalitis will meet a better fate than the virus isolated by a number of authors from poliomyelitis. The fact that other workers in the field cannot duplicate the results of the discoverers does not necessarily speak against the reliability of the discovery; still, if a test is to be useful, other workers than the discoverer have to be able to find the organism or perform the test. So far this has not been the case neither with poliomyelitis nor with lethargic encephalitis. If the discovery of Loewe and his associates proves to be true, it will facilitate the diagnosis of encephalitis, which at present is a very difficult task.

Emphasis is laid by Levinson¹² on the quality of changes of the cerebrospinal fluid in various diseases. The author believes that cerebrospinal fluid of various affections of the nervous system differ not only quantitatively but also qualitatively. He also believes that the presence of a sediment or pellicle in cerebrospinal fluid is an indication of a meningitis. This view is rather radical, but is claimed by the author to be based on experience. Levinson also is of the opinion that meningism produces only physical changes in the fluid, such as increased amount and increased pressure, but no chemical or physicochemical changes.

Gingold¹³ describes the following new sign for tuberculous meningitis: by flexing the head on the chest either bilateral or unilateral internal strabismus develops. If this sign proves to be present in all or the majority of cases, the diagnosis of tuberculous meningitis will be made much easier than it is at present. Everyone who works with children knows how difficult it is to make an early diagnosis of this condition; in fact, at times it is almost impossible to make a diagnosis ante-mortem. The reviewer, however, is rather skeptical as to the reliability of this sign. It seems to him that many conditions may produce the reaction described by the author and that it can in no way be taken as specific for tuberculous meningitis.

Traumata of the Newborn

Some interesting research has been done recently on hemorrhage of the newborn. Warwick¹⁴ found that in a series of thirty-six autopsies on stillborn babies, eighteen, or 50 per cent, showed definite hemorrhage in the dura over the brain or in the ventricles and that in eight of these thirty-six infants gross hemorrhages were found in other organs beside the brain. The author comes to the conclusion that hemorrhage of the brain is brought about by trauma in normal rapid deliveries, by congestion or asphyxiation in slow deliveries, or by disease of the child itself. Forceps delivery and advanced age of primipara mother, on the other hand, do not play as important a rôle as formerly taught.

This conclusion is interesting because until very recently we have been accustomed to attribute hemorrhage of the brain in the newborn and its resulting cerebral palsies to forceps delivery.

Foote¹⁵ strikes a new cord by suggesting that hemorrhage of the brain in the newborn is simply a manifestation of a hemorrhagic tendency in the patient. He, therefore, suggests that a coagulation test be done on the blood of all newborn infants. It is interesting to note that, simultaneously with the suggestion of Foote, another worker, Rodda,¹⁶ of Minnesota, has performed coagulation tests on the blood of newborn infants and found coagulation to be an important factor in hemorrhage of the brain.

A good deal of work has been done recently on the blood of infants. Happ¹⁷ tested the blood for iso-agglutinins and found that the grouping as present in adults is rarely present in blood from the umbilical cord. He also found that at birth and during the first month of life, iso-agglutination is rarely present, but that the percentage of infants in whom the iso-agglutinin group is established, increases with age, so that after one year the group is usually established, and after two years it is always present as in adults. The author believes that on account of the differences between the agglutination reactions in the blood of mother and child it is not safe to transfuse an infant from its mother without making the preliminary tests.

In spite of the increased figures on the chemical composition of the blood in adults and its change during disease, there are as yet no standard figures on the chemistry of the blood in infants and children. It is therefore interesting to know the observation of Chapin and Myers,¹⁸ who examined the blood in a series of 149 children, 38 of whom were nephritic, and 6 of whom were diabetic. The authors found that nephritis in children does not result in urea retention as quickly as in the adult. This makes the prognosis of nephritis more favorable in early life. Creatinin retention rarely occurs in children.

A new clinical picture has been described by Hess and Myers¹⁹ under the name carotinemia. This sign consists of a yellow discoloration of the skin on a diet rich in carotin, such as carrots, spinach, egg yolk and orange. The condition resembles mild jaundice, except that the sclera is not involved in carotinemia.

This clinical observation is interesting as it puts one on guard in making a diagnosis of icterus.

ILLINOIS CARE OF CRIPPLED CHILDREN

The number of permanent clinics for crippled children throughout the state of Illinois has increased to twenty-seven, and the need is such that a definite demand has been made upon these clinics for full instead of half-day service, and the clinics are to be held with greater frequency.

Hospitalization of these crippled children is not called for. For the most part they are not sick, and the environment of general hospitals is unsatisfactory. The provision for a hospital for crippled children for which appropriation was made by the last General Assembly will not be available for some time, during which interval the enterprise must be carried on by means of private subscription and individual initiative.

MEDICAL WORK IN PALESTINE

Palestine's first medical journal, "*Harefooah*" (Medicine) has recently made its appearance, published by the Jewish Medical Association of Palestine. The journal is quarterly and its first issue is dedicated to the memory of the Jewish physicians and nurses who "lay down their lives in the years of upheaval in the Holy Land."

The objects of the medical association, as outlined in the quarterly, are to strengthen and coordinate the medical forces of the country and to collaborate with doctors outside Palestine; to give the medical work a national as well as a human value; to prepare a native soil for Jewish scientists; and to help in the creation of the Hebrew University.

Medical work in Palestine has advanced rapidly during the past two years, stimulated by the American physicians and nurses with the American Zionist Medical Unit, who have taught the native members of the profession all the latest ideas in medical work and sanitation. Clinics are held by the American doctors, to demonstrate to the Palestinian doctors the most modern methods, and lectures are given at regular intervals.

The hospitals and clinics established by the American Zionist Medical Unit in Palestine are planned as the beginnings of the Medical College of the Hebrew University at Jerusalem, which Prof. Patrick Geddes, noted town planner of the University of Edinburgh, is designing.

OCCUPATIONAL DISEASES IN NEW YORK

The growing complexity of the problem of occupational diseases before the Compensation Boards is illustrated by a recent case decided in New York, in which an employee died from an occupational disease contracted in the industry but was denied compensation because the Act compensates only industrial accidents. The report of this case, appearing in the *Bulletin* of the New York State Industrial Commission, is of special medical interest.

Claim for compensation is made by the widow of Joseph A. Foster growing out of his death on March 6, 1919, as the result, as it is claimed, of an industrial accident. The certificate of death filed with the Bureau of Vital Statistics gives the cause of death as "arterio-sclerosis," contributory, "cerebral hemorrhage." The employer's proof of death gives the cause of the death as follows: "His constant handling of lead plates with frequent scratches on hands and working over metal pot inhaling fumes of molten metal caused lead poisoning."

There seems on all the evidence to be no doubt but that the deceased did die as the result of lead poisoning, and the only question to be determined is whether the poisoning was the result of the accident within the meaning of the Compensation Law or must be classed as an occupational disease.

In his opinion, Commissioner Lyon reviewed the evidence taken before the deputy commissioner showing that the deceased had worked in the electrotype part of the Star plant or in similar establishments for years; that in so doing he clipped the lead off the edges of the plates with a long pair of shears, and that he and other men engaged on like work were continuously cutting and scratching their hands from the lead. Several years before his death Foster suffered from carbuncles, which appeared on his hands one after the other. Witnesses gave their opinion that this infection was due to his occupation. Commissioner Lyon's conclusion follows:

The testimony also shows that the men who work in electrotyping, as the deceased did, are continuously cutting their hands and treating themselves with iodine and other washes, and the deceased's daughter testified that at the time of his last sickness he had cuts on his hands, and she also testified that he previously had cuts of this particular character.

The full picture presented by this testimony is that of a man who is thoroughly saturated with lead poisoning,

which is the accumulation of years of work in and about lead. No one was found who could testify to any particular accident which the deceased had. If he cut his hands at or about the time when he was last taken sick, the cut was so slight and so exactly in accordance with what was happening to him day after day, that it caused no attention either from himself or from anyone else. The deceased not only had the duty of working around the electrotyping plates, but he had worked for long periods of time over pots containing muriatic acid, which gave off very offensive and apparently very unhealthy fumes.

I am clearly of the opinion on the whole record that the death of Mr. Foster was the result of an occupational disease and not of an industrial accident, and I advise that an award be denied.

The Commission affirmed the opinion of Commissioner Lyon.

CONQUERING PLAGUE IN THE PHILIPPINES

Recent discovery of a number of isolated cases of the bubonic plague in the United States has quickened the public concern in fighting the plague in its primary focus and lends interest to a *Bulletin* of the National Geographic Society describing how the disease was conquered by American medical authorities in the Philippines.

"The United States drove the bubonic plague out of the Philippines as completely as it swept the yellow fever out of Cuba," says a communication to the Society.

"Bubonic plague was discovered at Manila December 26, 1899, and slowly but steadily increased up to December, 1901.

"The deaths in 1900 numbered 199, and in 1901 reached a total of 432. The disease was at its worst each year during the hot, dry months of March, April, and May, nearly or quite disappearing during September, October, November, and December. It will be noted that the number of cases in 1901 exceeded that in 1900 by 200, while the number of deaths was about two and a half times as great, and the percentage of mortality among persons attacked increased from 73.4 in 1900 to 91.7 in 1901.

"On account of the important part which house rats are known to play in the distribution of bubonic plague, a systematic campaign was inaugurated against these rodents in Manila. Policemen, sanitary inspectors, and specially appointed rat catchers were furnished with traps and poison, and both traps and poison were distributed to private individuals under proper restrictions. A bounty was paid for all rats turned over to the health authorities, and stations were established at convenient points throughout the city where they could be received. Each rat was tagged with the street and number of the building or lot from which it came, was dropped into a strong antiseptic solution, and eventually sent to the biological laboratory, where it was subjected to a bacteriological examination for plague.

"Buildings in which plague rats were taken were treated exactly as were those where the disease attacked the human occupants. The bacteriological examination of rats enabled the board of health to follow the pest into its most secret haunts and fight it there.

"With very few exceptions, there was no recurrence of plague in buildings which had been disinfected and renovated. As center after center of infection was found and destroyed the percentage of diseased rats began to decrease, and in January, 1902, when, judging from the history of previous years, plague should have again begun to spread among human beings, there was not a single case. In February one case occurred. In March there were two cases, as against sixty-three in March of the preceding year, and before April the disease had completely disappeared."

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

DISEASE PREVALENCE AMONG WAGE EARNERS

FROM figures supplied by sick benefit organizations of certain plants which are cooperating with the United States public Health Service there are presented in *Public Health Reports* of December 3, covering the first six months of 1920, tabulations of sickness frequency among industrial employees. Only those cases are included which caused disability of one week or longer. As the reports from these organizations were more or less discontinuous, the rates are computed for each month separately, and not for the full six months period. The percentages are based on the number of employees reported as holding membership in the various organizations during each month. While practically all of the reporting organizations require a physician's certificate naming the ailment causing disability, the correct diagnosis is probably not always reported; the figures, however, afford a fairly accurate idea of the more serious affections occurring among the working people.

If the cases of sickness which disable for at least a week should occur as often during a whole year as they did in each of the several months, the number of such cases by the end of the year for every one thousand persons would be as follows: January, 267 per thousand persons; February, 324; March, 133; April, 133; May, 94; June, 82.

Extraordinarily high incidence occurs in January, which is the more significant when it is considered that thirteen of the twenty-nine reporting associations represent men in the most vigorous period of life. These workers constitute definitely a selected group also, in that female membership is relatively small, venereal diseases are not included, and chronic diseases contracted prior to membership are eliminated. The figures, therefore, may be regarded as a *minimum* statement of the disabilities occurring lasting ten days or longer. The high incidence in February is attributed to a recrudescence of epidemic influenza. A marked seasonal variation is a conspicuous feature of the report.

The reports were again studied from the viewpoint of the frequency of specific diseases and groups of diseases. The outstanding causes of disability are found in the general, the respiratory, and the digestive groups,

these three groups comprising 86 per cent of the total sickness in February, fluctuating according to the seasonal variation to 60 per cent of the rate for all diseases in June. The monthly fluctuations in the incidence of all diseases, of the more important specific diseases, and of groups of diseases are indicated in a general way for each association. The respiratory diseases were greater than the rates for any other group, not only in January and February, but in June as well. The general diseases in every month except April were slightly less frequent than the digestive disturbances.

The most outstanding feature is, of course, the incidence of epidemic influenza. Next in importance were bronchitis, pneumonia, and diseases of the pharynx, principally tonsillitis. Rheumatism was most prevalent in April and May. For new cases of tuberculosis the rate varied between one and three per one thousand persons a year.

The reporting associations were classified according to size. While all showed the expected seasonal variation, the wide differences shown in the frequency rates for the various associations would seem to indicate strong reasons for a careful study of the causes of illness in the different plants, and of the conditions which gave rise to them. While the records of the several establishments are not sufficiently comparable to make specific deductions, the value of such statistics becomes plainly manifest in the problems they indicate. As such records accumulate, and as the sources of such definite and reliable data are extended, they should afford prompt and satisfactory means of obtaining current information of the incidence of disease among the wage earning population.

The tabulations presented represent merely a beginning in the publication of industrial morbidity statistics, and industrial plants everywhere are urged by the United States Public Health Service to cooperate in the collection of sickness statistics by furnishing reports periodically. No better means of really conserving health can be found than the systematic observation and analytical study of health conditions as they obtain in the environment of the wage earner, the mass of which data needs to be secured from industry direct. More detailed analyses will not only point out the health hazards that beset the wage-earner, but should indicate the point of attack and suggest measures of prevention.

S. P. M.

MEDICAL WELFARE WORK IN SMALL FACTORIES*

BY A. C. BURNHAM, M.D., NEW YORK CITY.

THE author has previously called attention to the neglect of first aid in small industrial establishments.¹ In the same issue of the periodical in which this article appeared there was published a report prepared by Dr. James E. M. Thomson upon industrial health service in a group of comparatively small industries located in a mid-western city of approximately seventy thousand inhabitants. The report covered 4,291 employees in thirty-four establishments, ten of which employed between 200 and 550 workers, the remaining twenty-four all employing less than 200. He found that not a single firm had an organized medical department and that only seven had first aid stations. That this condition is not limited to certain sectional areas is indicated by the results of a health study by the American Red Cross in a number of small cities located in central New York.²

In the New York survey there were a total of 2,291 employees in twenty-five factories located in small cities in the central part of the state, cities of approximately ten thousand inhabitants. The largest number of employees in one factory was 400 and the average number of employees was 92. Four of the factories had no first aid equipment, none of them had a trained nurse in attendance, and only two had any sort of trained attendants. Most of the employers reported that there was a physician "on call," but in many cases inquiry developed the fact that the physician's care was limited entirely to the treatment of emergencies. In answer to a question as to the character of medical and surgical care of employees the answer was almost invariably: "None beyond the requirements of the Compensation Act," or words to that effect.

Personal Inquiry Made

This study was made entirely through personal interviews with the owner, or manager, of the factory, so that certain inaccuracies which are apt to creep into reports based upon elaborate questionnaires sent by mail were to a large extent eliminated. In this connection it is interesting to know that, in the course of the conversation, every employer but one expressed the opinion that welfare work for employees had absolutely no effect on labor turnover or production.

In some cases, hospital care was available comparatively near by, but in three instances the nearest hospital was more than five miles distant. In one case the nearest hospital was more than twenty miles away.

In only one factory was any form of welfare activity encouraged. There was one factory, a steel company employing 210 employees, where athletics, dances, and annual picnics are financed in part by the employer.

It was estimated by employers that, in this group of 2,291 workers, there were 445 accidents every year. This figure errs on the side of conservatism because non-disabling accidents were, to a large extent, not included in the estimate.

If we examine the reports of welfare activities for large factories it is noted at once that, on the average, the

worker receives considerably more medical attention and a much greater interest is taken in his welfare in larger factories than in small factories such as covered by the above report.

For comparison a study was made of a single industry located in the same territory in which the above study was made. It was found that, although there are only a few hundred more workers than were represented by the above total, the preparation for medical attention was much more elaborate than was the combined medical attention for the above twenty-five factories. There were in this factory, of approximately three thousand employees, three first aid rooms with complete equipment, cots, stretchers, and necessary surgical supplies. There were a physician on part time duty, three nurses on whole time duty, and an additional nurse who worked as a substitute during part of the day, devoting the remainder of her time to public health work in the community. In a hospital near by the employer maintained three beds at all times for the use of the employees and their families. Except for the provision of compensation there was no actual promise of medical care of employees, but it stated that much actual help was given. There were numerous other welfare activities, such as rest rooms, club house, and athletic games. This employer, in contradistinction to the small manufacturer, said that he believed welfare activities increased production and caused a reduced labor turnover.

In the survey of medical care for industrial workers located in various communities in the eastern and middle western states, Selby³ found, as a result of his investigations, that the smaller industries were, as a rule, not well equipped for the medical and surgical care of their employees. He suggests that every establishment employing anywhere from two hundred to five hundred people is warranted in having a dispensary and, further, that such an establishment is justified in having either a part time or full time physician on duty.

When such a physician is on a part time basis, his service may be advantageously augmented by a trained female nurse or by a person who has been taught to handle the routine work under the physician's direction.

Large Factories Well Equipped

Dr. Selby found much better medical facilities in a number of larger factories. In nineteen establishments employing between 1,000 to 1,500 workers he found that more than one-third had whole time physicians. In seventeen of the nineteen places, there were well equipped dispensaries, and in all but one of these there was some trained person constantly in attendance. In still larger industries—employing from 2,000 to 4,000 employees—it was found that about half had full time physicians and that all but two had established dispensaries with a trained medical attendant constantly on duty.

In forty-five industrial establishments employing more than 4,000 employees there was only one which did not have a dispensary and only two that did not have either a part time or full time physician. The relation of the trained personnel to the employees is shown in Table I.

*From the Department of Health Service, Atlantic Division, American Red Cross.

1. Burnham, A. C.: Jour. Indust. Hygiene, October, 1920.

2. From hitherto unpublished figures of an industrial study made by Prof. R. W. Foley, Colgate University, for the Health Service, American Red Cross, August, 1920.

3. Selby, C. D.: Studies of the Medical and Surgical Care of Industrial Workers, Public Health Bulletin, 1919, xcix.

TABLE I.—AVERAGE APPROXIMATE NUMBER OF EMPLOYEES PER INDIVIDUAL IN WHOLE TIME MEDICAL DEPARTMENTS

Number employed	Physician	Attendant	Clerk
500 and less	225
500 to 1,000	462	800	325
1,000 to 1,500	1,257	1,260	566
1,500 to 2,000	1,498	2,350	1,400
2,000 to 4,000	2,191	1,331	1,686
4,000 to 10,000	2,695	2,350	2,600
10,000 and more	3,094	1,497	4,138
Average	1,632	1,598	1,786

From Table I it is apparent that the service of the physician reaches a greater number of employees in large establishments than in smaller ones. This is accomplished because, in many of the larger establishments, it is the custom to supplement the services of the physician by the employment of trained nurses. In addition, in large factories, one or more clerks may be advantageously employed for the routine clerical work.

Thus one large steel company, employing 30,000 workers, had for their total personnel: Four whole time physicians, one physician on call, twenty-six trained nurses, and four clerks. This is an average of about six thousand employees for each physician but less than nine hundred employees per unit of medical personnel. A large automobile factory employing 8,000 workers had five physicians, one trained nurse, and six experienced male attendants. This is an average of about 1,500 for each physician but only about 700 per unit of medical personnel. Another factory employing 18,000 had ten physicians, eleven nurses, six clerks—an average of 1,800 for each physician but less than 700 per unit for medical personnel.

Table II has been arranged to show in parallel columns the relation between the medical services in large and small establishments.

TABLE II.—COMPARATIVE MEDICAL CARE IN LARGE AND SMALL FACTORIES

	25 small N. Y. State factories small cities.	34 Nebraska employers in city of 70,000.	1 large silverware manufacturer N. Y. State.	40 large factories from Eastern Middle States.
Total employees....	2,291	4,291	3,000	57,800
Av. No. employees	92	126	3,000	1,445
Full time physician	None	None	None	35%
Part time physician	None	None	One	45%
Physician only on call	96%	No record	Also one on call	30%
Dispensary	4%	71% have first aid rooms	Has 3 first aid rooms	90%
Trained nurse.....	None	None	4	52%
Experienced attendant	8%	"several"	None	28%
No medical attendant	92%	No record	7.5%
Dentist	None	No record	No record	10%

In the preparation of Table II no attempt has been made to take into consideration the character of the medical service. It is quite possible that in some factories employing a part time physician medical service might be better organized than in another establishment with a full time physician; but in general it may be said that a full time service is better than part time and this is in turn much more desirable than any form of service under which the physician is called only when needed. In the case of most factories employing less than five hundred employees it has been found impracticable to employ a full time physician. While a few factories of this size,

especially those in isolated communities, have built up a full time medical service, it is felt by most employers that the expense involved is too large to warrant the institution of any very elaborate form of medical care. In the larger factories having well equipped dispensaries the outlay for equipment is considerable. Even before the present high prices the necessary cost of equipment for an up to date dispensary with x-ray and laboratory equipment might easily exceed \$5,000. Today the price would be much more.

However, such elaborate supplies would not be required for a small factory. In many states the installation of a first aid kit with one or more trained assistants is required by law.⁴ This equipment is rarely sufficient for more than the minimum emergency care and more complete equipment is desirable. Reasonably satisfactory equipment for minor surgical treatment and emergencies could be secured today for less than two hundred dollars, and five hundred dollars would secure a fairly well equipped physician's office. Of course in such cases arrangements for x-ray and laboratory examinations would have to be made at a near by hospital.

What Service Is Required

In order to meet the requirements for medical and surgical service of smaller industries there have been several plans suggested. The author has already suggested¹ the establishment of community first aid stations in order to meet in part the demand for medical care of industrial employees.

Dr. Thomson, having in mind the requirements of a city of 70,000, suggests a cooperative industrial bureau with rather an extensive personnel consisting of an executive head under whom were directors of employment, insurance and medical care. For the treatment of employees he divides the bureau into two groups, the first of which is apparently a central group to which are attached a professional personnel consisting of physicians representing the various specialties, nurses, and attendants. The second group of professional personnel presupposes the division of the industrial work of the city into districts in each of which is a district surgeon whose duty it is, with the aid of a nurse, to attend the injured and sick in the various industries, referring severe injuries and doubtful ailments to group one for diagnosis, treatment, and hospital liaison.

Dr. Selby, in his study, also suggests a cooperative medical service for smaller industrial establishments. He calls attention to the fact that in some cities there are already being established organizations of employers of labor to furnish information in such matters as traffic, casualty insurance, and employment and he believes that this could be extended to cover medical service. In some cities from a strictly commercial standpoint physicians have organized a series of medical treatment stations in various districts of the city, in order to care for compensation cases. These have met with more or less success depending largely upon the personality of the physicians engaged in the enterprise.

4. N. Y. State Industrial Code, Rule 178 and 179: The New York Industrial Code requires that "in every factory employing more than ten persons, in which power driven machinery is used for manufacturing, there shall be provided a first aid kit at all times, free of expense to employees," and that "in every establishment where a first aid kit is to be maintained, at least one person shall be instructed by a physician or trained nurse how to apply first aid to injured persons and shall have charge of the first aid kit and its maintenance."

5. The American Red Cross Health Center, A. R. C. 1012, Sept. 1, 1920.

6. The per capita expense of a large shoe factory in New York state is approximately seventy cents weekly, or thirty-five dollars yearly per employee. Full medical attention is furnished to the employee and his dependents.

The experience of the Bush Terminal Company, in Brooklyn, has been most instructive. The Bush Terminal buildings are large reinforced concrete buildings so arranged as to house a number of manufacturers. The Bush Terminal Company has established a well equipped hospital on the ground floor of one of the buildings. The services of this hospital are available to every employee in the building or in the vicinity. While treatment is limited largely to compensation cases, it might easily be extended to cover physical examinations and treatment for sickness.

There are many locations in every large city where hospitals similar to the one at Bush Terminal might be profitably established. However, it appears that the chief difficulty is that the great majority of employers in small establishments have not reached the attitude of mind in which they are willing to spend sufficient money to maintain an adequate medical service. As there are probably in the aggregate many more persons employed in small establishments than in large, it would appear that it is necessary to reach and convince these smaller employers in order to start a cooperative plan of this sort from within the group.

Cooperative Plan Feasible

The organization of such a cooperative plan from sources without the group of employers is apparently both feasible and practicable. It may arise from one of three sources: (1) physicians; (2) state; (3) voluntary organizations.

The inauguration of this plan from a commercial standpoint by physicians has already been mentioned. Several physicians, joining together, start a dressing station in the vicinity of a group of factories. They treat compensation cases for the regular fees and, in some cases, give additional medical care for a fixed per capita fee. In the main this plan is not considered desirable, as the results obtained are largely dependent upon the character of the men who start the enterprise and as the commercial element is apt to be so great as to defeat its own purpose.

The organization of a cooperative medical service by the state or the municipality is indicated by the fact that, in certain cities, the local department of health has already started industrial health stations. These, to date, have been limited largely to the study of industrial diseases and industrial hygiene, but they might be easily extended to cover accidents and general medical care of employees.

In small communities a cooperative medical service, in conjunction with a voluntary health organization, such as the American Red Cross or a local health organization, offers certain very definite advantages. As the cooperative plan may be said to be in the formative stage, it is much better that during this stage, which is to a certain extent experimental, the plan should be developed by a voluntary organization rather than by city or state. Mistakes in regulations and plans for administration are much more easily corrected in a voluntary organization than when under public authority. In addition, the participation of a well known organization, such as the Red Cross, would avoid to a large extent suspicion and distrust on the part of the wage earner. Even when inaugurated by the employers, welfare work is sometimes made difficult because of an ill-defined suspicion on the part of the employee.

The American Red Cross has inaugurated the policy of the establishment of health centers⁵ for the dissemination of health information and education. In certain communities where there are no hospitals or dispensaries the health center is logically the community first aid station.

Through the medium of a cooperative industrial service it may frequently be possible to establish a Red Cross Health Center with a well equipped first aid room, for the service of the general public. In other words, the surgical clinic may be established as part of the health center and the surgical care of the injured in industry undertaken by physicians and nurses in the employ of the various industries, while the center as a whole is devoted to the needs of the general community. Naturally, the employers pay a proportionate part of overhead expenses of the health center. By this method it may be possible to locate a completely equipped emergency room in health centers in smaller cities, which might otherwise be omitted because of the difficulty of financing such a project. The intimate relation that such a center would bear to the injured workmen could not fail to react favorably toward the health education of the entire community.

In the carrying out of any plan for cooperative health or welfare work, the consideration of expense is of the utmost importance. It has been so difficult even in the larger factories to determine the exact cost of welfare work that it is doubly difficult to estimate the cost of installation of any form of cooperative health station. Dr. Harry Mock in an examination of a number of industrial establishments found that the expense for medical care varied from less than two dollars per capita yearly to more than seventeen dollars. This fluctuation to a large degree was due to the varying extent of medical care which was furnished employees.⁶

In a small community of approximately a thousand workers in several separate industries, a centrally located surgical dispensary with a nurse in attendance and a physician on part time duty might be run for a total of two or three dollars per year for each worker served. This would naturally be in addition to the physician's regular charges for treatment of compensation cases. If the per capita expenditure was increased to one dollar per month for each employee, the plan could be greatly extended so as to include visiting nursing in the home, dispensary treatment for illness, hospital care for certain cases and certain other welfare features.

Dispensaries Cooperate

In smaller cities where there is no local hospital, it may be possible and practicable for the community to establish a cooperative dispensary, in part for the general public and in part for the special benefit of local employees. This would be financed by equitable contributions from the public treasury, from the local industries, and, in certain cases, from private individuals.

If we accept the theory that it is cheaper to keep an individual healthy than it is to cure him after he becomes ill, it is evident that cooperation for medical treatment tends to emphasize the advantages of preventive medicine. In an interesting experiment started by a large industrial insurance company it has been found that the introduction of a visiting nursing service for all industrial policy holders has apparently tended to lower death rates among policy holders. It would seem that some form of industrial medical service such as suggested above would not only diminish the total period of disability for industrial injuries but would act to raise the general health level of the wage-earner, thus benefitting the community as a whole.

Many people resent the fact that a contemptible microbe may kill a genius before he comes of age, and that paltry flies put a drag on the wheel of the chariot of civilization.—Thomson.

SHOP STANDARDS AND FATIGUE*

By BERNARD J. NEWMAN, CONSULTANT, UNITED STATES PUBLIC HEALTH SERVICE (RESERVE), PHILADELPHIA, PA.

SUFFICIENT progress has been made in the determination of the causes of industrial over-fatigue to warrant the introduction of plant programs for its control. To what extent the formation and adoption of these programs should be left to the initiative of plant managers or should be imposed upon them by governmental regulation of state or municipal origin may be a mooted question. That such programs, when scientifically determined, yield returns not only in better working conditions and in better wages for employees but also in larger profits in production for employers, cannot be doubted; that is, programs for the elimination of industrial over-fatigue, when based upon correct principles and constructed by experimental methods, are financially profitable to all concerned in industry today.

In making this assertion I am relying on recent determinations made in laboratory and field studies by researchers, largely officers or consultants of the United States Public Health Service or other researchers attached to the English Health of Munition Workers' Commission, as to the causation and control of fatigue.

The Term Fatigue Is Defined

Fatigue may be defined as an inhibition placed on body activity because the capacity to function has been, for a temporary period at least, reduced or broken down as a result of an output of bodily energy in excess of that compatible with normal functioning. It may be a "diminished capacity for work which is the result of previous work," as Prof Frederic S. Lee¹ phrases it—a definition which he points out has its decided limitations; or it may be the "sum of the result of activities which show themselves in a diminished capacity for doing work," as Sir George Newman² defines it. To restrict the definition to work activities would not be scientifically accurate, as other causes play a part, varying in scope and in degree. These causes, which we will consider more in detail later on, must not be minimized.

Industrial fatigue is concerned primarily with conditions which arise within industrial establishments or in industrial processes, responsibility for the elimination of which rests primarily with the establishment, and gains from such elimination necessarily accrue to the establishment first and to society afterward. In the absence of specific designation of other fields of fatigue causation, reference hereafter in this paper will be industrial over-fatigue.

To appreciate the fatigue problem in industry and to determine an acceptable program for its elimination or

Undue fatigue, wherever it occurs, must be regarded either as a symptom of disease, a sign of misdirection or waste of energy, or a reliable index to unhygienic working conditions of shop or factory reducing the efficiency of the worker.

If adverse mental processes are responsible for over-fatigue, the remedy is a question of placement, of fitting the worker to his job. If the tired feeling cannot be charged to maladjustment, then diagnosis, treatment and better adaptation are in order. If the fatigue results from air poisoned from processes of manufacture, or vitiated from overcrowding; from monotony, or speeding up—then it may be said to involve society collectively and must be charged to industry as a social wrong.

Data are not complete for all industries, but sufficient study has been made to correct the more serious inroads on the welfare of the workman.

reduction to the point where it neither retards production nor increases the cost thereof, we must arrive at a common understanding of the physiological changes in the body as a result of prolonged muscular activity.

Life is a continuous process of metabolism. Constituent parts of food taken into the body are distributed to the cells, where they are converted into protoplasm or furnish fuels in easily oxidizable form for the generation of heat and energy. At the same time there is going on within the body as a result of its activities a change of

matter into lower forms no longer serviceable to life, the waste products of activity. The strength and activity of the body,—the health of the body,—depend upon the adequate supply of food and oxygen to the cells and the activity of the cells in the transformation of this food in the processes of anabolism into living protoplasm or its oxidation in the production of heat and energy; but they also depend upon the removal of the waste products of katabolism, i. e., of destructive metabolism constantly going on, in intense muscular activity more so than at other times, into lower forms finally to be eliminated as waste. If as the result of energy output the balance between intake, output, and waste removal is no longer maintained, retardation in the elimination of waste products takes place and fatigue results.

When, therefore, the statement is made that fatigue is due to long continued use of a muscle or group of muscles, what is really meant is that in the constructive and destructive metabolism of the body such activity on the one hand creates in the muscle such waste products as carbon dioxide, lactic acid, or possibly other metabolites characteristic of fatigue. Thus there is a chemical change. Moreover, this muscle-waste, accumulating faster than it can be removed, causes what corresponds to a clogging of the muscle, and diminishes the amount of oxygen and glycogen supplied thereto; thus the cells are unable to function satisfactorily, for it is to be remembered that coincident with muscular contraction there is a consumption of oxygen and oxidation of glycogen. A muscle starved of these supplies ceases to function normally and fatigue is produced.

In the functioning of the body all parts are interrelated. A strain on one organ may ultimately reflect itself upon others. One set of muscles over-exercised requires from heart, lungs, the glands involved, and from the nervous system anabolic assistance. The blood and lymph, over-charged with waste in the attempt to remove the katabolic products of the overworked muscles, distribute to the rest of the body these waste products and induce throughout the signs and symptoms of the originally tired muscle. Fatigue then becomes general.

This brief explanation of the physiological basis of fatigue has purposely omitted several modifying factors.

*Read before the Ninth Annual Safety Congress, Women in Industry Section, Milwaukee, Wis., September 29, 1920.

2. Reports of the British Committee, Ministry of Munitions, on the "Health of the Munition Worker," p. 16.

The effect here assigned does not come in a straight line from the cause. General fatigue may not appear, although the exercised muscles may themselves be fatigued. Before the effect is transmitted to the other parts of the body, a rest period may elapse wherein the blood and lymph may remove the excess waste and restore the working power. This is the normal method of functioning the body, and rest is the great restorer of the "tired-out" person.

In the presence of fatigue the body possesses within itself powers of momentary restoration. Witness the reaction of the soldier on a hike to the rhythm of music, or the football player or the Marathon runner to the presence and cheers of the crowd. There is evidence sufficiently authentic to establish the fact that excitement may remove temporarily the chemical cause of fatigue. Cannon³ states that emotional excitement tends to stimulate the discharge of adrenin, a vasomotor stimulant secreted by the adrenal glands. He points out that adrenin "is able to bring a rapid recovery of normal irritability of muscle after the irritability has been lessened by fatigue." "What rest will do only after an hour or more, adrenin will do in five minutes or less." By it the strength and rapidity of the heart beat are increased, the blood is driven through the fatigued muscles, carrying away thereby the waste products which inhibited their freedom of action.

How Fatigue Is Manifested

Strange as it may seem, it is not always easy to tell when fatigue is present, because its symptoms may be masked. "That tired feeling" which is advertised against, if experienced, does not necessarily register fatigue, but may be a symptom of other diseases. There necessarily follows work a normal amount of weariness which is healthful and makes a well earned rest enjoyable. This readily yields to rest. There is a fatigue that attacks a muscle quickly, following undue exertion. There are certain symptoms which the diagnostician groups in his effort to segregate the type of disease afflicting his patient, seemingly well phrased by Dr. Kober:⁵ "The general effect of overwork and chronic fatigue are characterized by loss of appetite, anemia, digestive derangements, respiratory and cardiac affections, fatigue neuroses, neurasthenia, and general deterioration of health." Over-fatigue may be present to the extent of producing symptoms without the subjects being aware of the true cause. It may appear in irritability, in errors of judgment, in mistakes, or in retardation of thought due to lapses of memory.

However, the important facts to remember are that over-fatigue has a causation resting upon the physiological processes of the body; that its presence is sometimes cloaked; that a failure to recognize its social and industrial causes, as a first step in a plan to eliminate them, often results disastrously to the individual and to industry.

The Cost of Fatigue

Fatigue costs may be expressed in terms of the effect upon health, longevity, safety, labor supply, employment stability, industrial contentment, productive efficiency,—*i. e.*, alertness, speed, accurate work, minimum waste,—as well as output and profits. Evidence to support the foregoing will not be introduced here. Certain facts, however, are illustrative. Recent studies of the working conditions of the foundry trades made by the Office of Industrial

Hygiene and Sanitation of the United States Public Health Service show that where the molders work at piece work there are a greater number of physical ills than where they work at day work, other factors not differing to any marked extent. It is a reasonable postulate that where excessive fatigue is produced and prolonged in labor for any length of time, vital resistance is reduced and the body is less able to resist disease. It is a noticeable feature of production studies that the maximum depression of the output curve is reached after the middle of the shift, although in shops where there is a definite attempt to limit output, the production curve often does not show any material change at any time during the day.

In two plants working on an eight and a ten-hour day respectively, where intensive studies were recently carried on by the Public Health Service, it was a noticeable fact that "while in the final hours of the day accidents fell with the decline of output," yet the presence of over-fatigue interfered with a parallel decline. There was, in the ten-hour plant, a greater rate of fall in production than in accidents, the accident ratio for such plant actually increasing; that is, although both accidents and production decreased, yet the decline of accidents did not keep pace with the decline of production making the number of accidents in proportion to the number of pieces produced greater in the last hour than in the previous hours.

As in case of over-fatigue and sickness so in over-fatigue and decreased production, the cause and consequence are practically self-evident, not needing citations either to illustrate or to demonstrate. Indicative though, of the data here, is Dr. H. M. Vernon's report⁷ on some experiments which he conducted in a tin plate plant in South Wales. The workers were lifting weights of forty to eighty pounds by long tongs in a temperature of 110 degrees Fahrenheit. They worked in five or six shifts of eight hours each. Plant conditions forced changes of shifts at times to six and four hours respectively. When the work results were analyzed it was found that when three of the eight-hour shifts were distributed into six four hour shifts, the production increased 11.5 per cent. The American Committee studying fatigue during the war found that the output in one large munitions plant was practically *nil* during the last hour of a twelve-hour night shift. The English Committee working in the same field found among a selected group of employees an increase in production of 9 per cent when the working hours were dropped from 62.2 to 45.6 per week; while with another group a change from 58.2 hours per week to 51.2 increased the output 21 per cent.⁶

In a discussion of economic losses from over-fatigue a writer recently gave a mass figure which challenges consideration, not because of any proof of its accuracy so much as because it is both spectacular and logical. He estimated the loss from fatigue to the nation as not less than twenty cents per worker per day per year. In order to grasp the significance of this apparently slight loss, recall that the Bureau of Census estimates there are about forty million workers in the United States. The normal working year is three hundred days. On the basis of this estimate the monetary loss to the nation from over-fatigue would approximate \$2,400,000,000 per year. Translated into lost time, allowing an average wage of five dollars per day per worker, which is a high average, all workers considered, this would mean a lost time from production of the equivalent work of 1,600,000 workers for one year. If one were to carry this out further and

count in all the losses in sickness and accidents, to which fatigue is a predisposing or exciting cause, as well as those other losses due to turnover because of the disinclination of certain groups of workers to do hard work, the dissatisfaction which leads to sabotage and like losses, to the incidence of which fatigue is a contributing cause, then the drain upon society and upon the industrial group in society would amount to almost unbelievable totals.

Based on the capacities of the workers and not on the capacity of the machine, there is apparently in plant production a law of diminishing returns for energy spent, and a point is reached beyond which labor becomes less profitable. However, the massing of the probable losses in such a spectacular manner, while undoubtedly trustworthy and attendant upon or resulting from a lack of appreciation of the law of fatigue, does not convince the individual employer of the need to analyze his own plant. The loss is a national one which warrants a nation-wide preventive program. The problem which it presents to the average employer, alike important to the employee, is how so to control fatigue-producing conditions and processes as to enable efficiency to be maintained at a minimum cost in health and welfare to the worker and to the state.

Tests of Industrial Fatigue

It may be rightly assumed that the foregoing conclusions are founded on scientific determinations. These determinations have not been made by one set of researchers nor confined to one school of thought.

In the United States physiologists and physiological chemists attached to leading universities have been and still are experimenting in this field, originating and developing standard tests for the determination of fatigue and the analysis of the physiological and chemical changes accompanying fatigue. In industrial plants and elsewhere practical efforts are being made to devise ways to measure abnormal fatigue and to eliminate it. There is an extended literature⁸ on this subject. Some publications are wholly theoretical, while others deal with tests made and results obtained. The examples here given are illustrative only of types of researches pursued.

Experiment With Typical Tests

These types may well be divided into at least four groups: (1) Laboratory tests touching physiological, chemical, and bacteriological reactions to labor causing over-fatigue; (2) factory tests in regard to production; (3) physical tests upon employees to determine their capacity for arduous labor; and (4), a miscellaneous group including all tests of other character.

Laboratory Tests—Treppe

In the first group will fall tests made with animal muscle. The muscle given a definite load to carry is periodically stimulated by slight electric shocks and undergoes a successive contraction and expansion as shown in varying wave lengths when graphed. Such a muscle, functioning somewhat as in the body, gives a curve with a treppe similar to that formed by the production curve in an output study; that is, there is a slight climb, followed by a steady decline after the peak has been reached. Coincident with this activity a waste product is created which, under continued muscular activity, inhibits action and causes the decline shown in the curve. Under chemical tests this waste gives a lactic acid reaction. Other waste products are also distinguishable. The interesting

feature of this test is not only that it so closely followed the production curve of muscular work in a factory in the early rise followed by a decline, but that when the muscle is washed with a salt solution, the waste is removed, and the ability to function again is restored. Too close an analogy between the laboratory experiment and the normal function of the industrial workers in the plant cannot be made, for the former is not controlled by a directing will as is the latter and cannot simulate greater or lesser activity by a control of the output. Many experiments have been made from time to time in a similar direction to determine the nature of the fatigue producing substances found in the muscles.

Changes in Blood and Urine

Scott¹⁰ summarizes a number of kindred experiments made by such men as Lee, Burridge, Tisse, Fletcher and Hopkins, Ranke, as far back as 1865, Garrett, Colvin, Dunlap, and others. Laboratory studies of live animals were made by Hastings¹¹ to determine the possible relation of the bound CO₂ in the blood to fatigue. Dogs were made to run in a treadmill at a ten-mile rate until fatigue was induced. "Blood was drawn from the jugular vein," Hastings states, "without exposure to air, oxalated and centrifuged. The reaction of the plasma was determined electrometrically with a Clark electrode. In all cases a fall in the bound CO₂ followed exercise." While the extent of the fall varied with individuals, yet repeated tests of the same subject yielded practically the same fall under the same approximate amount of exercise. Hastings made further tests to determine whether a urine examination would yield data for measuring fatigue. He made observations upon Marathon runners, bicycle riders, and surgical patients resting in bed while recovering from simple operations. The results, which showed slightly higher acidity among those who had been through strenuous exercise than among those who had been resting, were nevertheless of little value. In subjects intensely fatigued the hydrogen-ion concentration of the urine invariably showed an increase.

The Incidence of Bacteria

The effect of fatigue in the incidence and severity of bacterial diseases is shown in the experiments of Emery.¹² While rats fatigued by a revolving cage were exposed to anthrax they showed more susceptibility than other rats similarly exposed, but which had not had their resistance broken down by excessive labor. De Sandro made similar experiments with dogs, guinea-pigs, and rabbits, according to Rosenau,¹³ who adds: "Under the influence of chemical changes induced by the physical strain . . . the defensive powers were much weakened; phagocytosis was reduced, and also the chemotactic power of the cells, the bacteriolycina, antitoxins, agglutinins, and opsonins showed a marked falling off."

Fatigue and Muscular Tonus

Dr. A. H. Ryan¹⁴ has experimented with an apparatus for recording the tension needed to cause a given extension of certain groups of muscles, hoping thereby to ascertain the effect of working conditions, such as hours of labor and work processes. His apparatus for testing the pectoral muscles consists mainly of metal slings, with cord

and pulley, and a spring balance delicately adjusted. He found that strenuous, long continued work decreased the muscle tonus; also short, hard, heavy work gave a quick decrease in tonus; i. e., in the readiness of the muscle for ordinary work under normal stimulus. Loss of sleep reduced tonus. Excitement overcame the effects of heavy work, this result having also been noted in connection with the analysis of the effects of adrenalin.

Tests of Factory Output

Factory tests are more familiar to the average person. They range from the simple output tests where the quantity of production is determined on an hourly, daily, and weekly basis. Automatic registers indicate the output for any selected period. The output test is not always indicative of fatigue. Even a decline in the output curve does not tell the true story, unless along with it is taken a power consumption test. Florence and Ryan¹⁵ have clearly shown that the latter is best made when the machine has its own motor, rather than power furnished from a central system and shafting. As previously stated, output curves may be discarded where soldiering on the job is practised, except perhaps as an index of such possible soldiering.

Spoiled Work an Index

Another test which has been used to corroborate the output test is that of spoiled work. With decrease in attention goes an increase in mistakes, as shown in the number of discards in the total product.

The Correlation of Accidents

From previous statements it will be recalled that there is a correlation of accidents, absenteeism, turnover, and fatiguing labor. In two factories where comparisons were possible workers on ten-hour shifts showed an absentee record of 3.15 per cent of the total working time, while in other factories on an eight-hour shift the percentage was only 1.53 per cent. Some factors were not eliminated here which are responsible perhaps for a greater difference than really exists, but the figures approximate accuracy sufficiently to make the data comparable.

Cinematograph Studies of Motions

Cinematograph records have been taken for the purpose of eliminating unnecessary motions. When such eliminations enable the employee to establish rhythm in his work, with the intermittent interruptions in the continuity of the operation, fatigue seems to be correspondingly reduced. Florence and Ryan¹⁶ suggest, as the result of tests made with the automatic rhythmometer, that rhythm, while maintaining the output curve to the end of the day in a lathe operation, yet seemed to mask fatigue. Physiological tests apparently indicated the presence of fatigue notwithstanding it did not assert itself in restricted production. Their test is described further on.

Industrial engineers are conversant with the adaptation of the principle of this test in the program of scientific management as set forth by Taylor in his standardized motions and regularized rest intervals for jobs of certain types.

Tests on Physical Basis

The more important tests as to practical value are those to determine the capacity of the worker for the job. These are: Mental, for intelligence, accuracy of judgment, and alertness; physical, for past history as to defects, and

for present complaints and current sickness. Such tests roughly indicate the presence of fatigue or the need for more intensive investigations into fatigue creating conditions.

Muscle Tests

E. G. Martin¹⁷ has tried out muscle tests for determining body strength. These tests are made in working clothes. A spring balance registers in pounds the strength of eight important muscle groups, and this record is converted into an index of physical working capacity by multiplying the total by 6.67. For effectiveness the test requires a job analysis, setting forth the body strength needed for each job and arrived at by averaging the strength of a group of workers on similar jobs. By making records over a more or less extended period, eliminating those engaged in such work but unfitted for it, as shown by later physical re-examinations, a standard and minimum strength below which it is unsafe to go is ultimately ascertained. Dr. Spaeth would improve this test by a formula which is a ratio to be obtained by dividing the strength total by the weight. Thus, workers of given weights would have to register a ratio corresponding to that established for the mean group.

Miscellaneous Tests Employed

Among the tests now being perfected the test of rhythm promises results which may seriously disturb previous opinions. Almost every writer on fatigue mentions monotony, or constant repetition of the same task, as the cause of fatigue. Florence and Ryan¹⁸ have made some tests of the effect of rhythm in industry. In measuring rhythm they attached an automatic rhythmometer to the machines. A signal magnet recorded variations. A mean was obtained by graphing the time and the output of a selected number of workers. A coefficient curve was made for a comparison of rhythm. Certain attempts were made to find modifying conditions which would interfere with the rhythm. They have summarized the results of their test as follows: (1) "By relieving attention" of the worker to his task, rhythm helps to reduce fatigue in the day's work"; (2) "by rendering more uniform metabolism and by the recovery involved in the operation" the effect of the work is more evenly distributed; (3) "by masking fatigue effects" more even distribution of output is obtained; and (4) by uniform motions and eliminating unnecessary motions, accident frequency is reduced.

Industrial Causes of Over-Fatigue

Manifestly, fatigue is a physiological reaction that can be measured, though there are many refinements in measurement which must be worked out in the laboratory and in the plant. It is true that the physical condition of the worker, his habits, and his activities outside the plant have a marked influence on his reactions to working conditions. If injurious, they make the effect of plant fatigue processes more acute. For this reason industry cannot be charged with responsibility for all cases of acute fatigue; but the working conditions and processes causing extraordinary fatigue can be segregated, and will yield to plant program for their correction. Such a plant program, which may be expressed in terms of shop standards, will include features to correct both the direct and indirect causes of fatigue. Distinction between these types of causes is made in that those grouped as direct, acting immediately upon cell life of the muscles intimately involved in the process of labor, create within the cells

the waste toxins previously referred to, thereby inhibiting their normal functioning. Those classified as indirect react upon the normal functioning of the organs of the body, and by inhibiting such normal functioning, ultimately interfere with the activity of the muscles necessary in the performance of the particular occupation in which the work is engaged.

Direct Causes of Fatigue

To summarize, the working conditions which may be classed as direct factors in fatigue causation are of such types as are commonly associated with muscular strain and which arise from continuous lifting, as in the case of laborers loading pig iron all day; or from long standing, as with bench hands on filing or weavers operating a dozen or more looms; or among employees engaged in processes where they labor in cramped positions, as garment workers; and workers who have a hard, continuous use of the same set of muscles, such as operators by foot power or sewing machine. To this class also belong those operations calling for continuous sitting in faulty postures which interfere with metabolism—usually on poorly designed chairs—as with clerical workers, accountants, and tobacco wrappers, as well as those other operations where the hours of labor are long and the work is continuous without intervening days of rest, or where the work is characterized by monotony without the relief afforded in rhythmical action. But the direct causes of fatigue include activities in places where muscular effort is not only imposed by the job itself, but such tasks or others in their vicinity produce excessive noises, as in the case of riveters using pneumatic hammers which tend to affect injuriously the delicate mechanism of hearing and possibly aiding in inducing fatigue in the body by the vibrations incident to the processes which give forth the excessive noises. Included in such direct causes are excessive temperatures with high relative humidities, as in mines and laundries, or fluctuations in temperature with extremes of heat and cold, as in steel mills or pickling rooms. Furthermore, such working conditions include occupations where light intensity, gloom, or glare, all fatigue the worker through eyestrain.

Indirect Causes of Fatigue

The foregoing classification of the direct causes of fatigue is intended to be illustrative and not a complete list of factory operations having this undesirable result. There are other causes of fatigue which, for the lack of a better term, we characterize as indirect; these arise from such working conditions as are found in operations creating air dustiness,—that is, in abrasive manufacturing, grinding, polishing, and sand-blasting. Here fibroid changes in lung tissue occur, restricting the normal function of the lungs or making them more fertile soil of tuberculosis. Similar operations creating fumes, gases and poisons too numerous for illustration, break down cell life, create undue amounts of waste, and overcharge the processes of waste removal in such wise as to inhibit normal functioning. To these indirect causes of fatigue may be added inadequate and insanitary toilet and drinking facilities; the absence of rest rooms for women workers or rest periods for operatives engaged in heavy labor; unsympathetic management, unattractive or repulsive work-rooms, accident hazards; congested occupancy of work-rooms, which facilitates the spread of epidemic diseases and unscientific placement of employees. But perhaps a factor as great if not more important than any other in contributing to industrial fatigue is the absence of industrial hygiene and provisions for medical and surgical re-

lief to provide for the physical welfare of employees, to note, reduce, or correct physical disabilities, or to treat minor ailments not sufficient to debar the worker from employment, yet capable of retarding maximum production.

Fundamentals of a Plant Program

These, as we have just said, are examples, only, of working conditions common in varying degrees to all industries, which fall within the groups of direct and indirect causes of fatigue, and which readily yield to a program when the management is alive to the importance of the human factor in production.

If a plant program is to be adopted, at least three steps are essential. I have discussed these at other places, have seen them tried, and have yet to find them wanting. First, there should be a physical examination of all applicants for employment, in order that their physical capacity may be known to the employment director, this examination to be followed periodically by re-examinations and replacements according to the health of the worker. This physical examination is in addition to the usual training and experience examination. Second, there should be a physical examination of the jobs, to find just what mental and muscular ability is required for maximum efficiency in output. Third, there should be a physical examination of the plant, to discover the working conditions which may injure the health of the worker, increase unnecessary fatigue and reduce output.

From such plant self-knowledge and from the program which it suggests, humane working conditions and mutual profit accrue to employer and employee.

OCCUPATION AND TUBERCULOSIS

Diseases of occupation are everywhere assuming more and more importance, according to George M. Kober, M.D., in *Public Health Reports*, and it becomes a public health problem to determine by thorough study the relative health risks of the several industries and to formulate rules for the removal or mitigation of existing evils. Persons habitually engaged in hard work, especially indoors, present a greater amount of sickness and a higher mortality than persons more favorably situated, and the character of the occupation may influence the prevalence of certain diseases. Sickness, hurry, worry, chronic fatigue, loss of sleep, vice, and dissipation, insufficient and improper food, insanitary homes, lack of pure air, all favor the development of tuberculosis. The latest occupational mortality statistics for the United States show that the mortality from tuberculosis in agricultural pursuits was 8.7 per cent; among bookkeepers and accountants, 22.5 per cent; and in servants and waiters, 27.4 per cent.

A study is made of proportionate mortality in specified industries from tuberculosis of the lungs brings out the importance of such factors as physique, habits, exposure to dust, social conditions, and standards of living, and but serves to emphasize the importance of personal hygiene and general sanitation, as applied in the homes and workshops of the Nation.

If we find upon candid examination, that even under self-direction, there is still much machine work which offers no outlet for creative energy, we can vary the work. And we can shorten the work day to a point where a compensatory leisure can offer the time needed to foster healthy activity which is interesting and spontaneous.—Ordway Tead.

DIAGNOSIS AND TREATMENT OF DISABILITIES OF THE BACK*

BY JAMES WARREN SEVER, M.D., BOSTON, MASS.

WITH the extension of compensation laws which are now in force in forty-two states, four territories, and under the Federal Government, physicians are seeing many more injured cases early as a result of the working of the medical provisions of these laws. Just what percentage of these injured workmen represent injuries to the back is not available, but it must be large. Besides seeing the cases earlier as a rule, there is a greater responsibility and necessity of making an accurate diagnosis in any given case in order to give the insurance companies or the state departments having jurisdiction a clear idea as to the nature and extent of the injury, and also its probable duration in terms of disability. This is not easy to do.

Before taking up the so-called traumatic injuries to the back as the result of these industrial accidents, it is important to consider the not uncommon types of painful

ments. The center of gravity falls in a line running from the tip of the mastoid through the front of the shoulder, great trochanter, just back of the patella, and about an inch in front of the external malleolus. Any variation from this normal poise implies muscle and ligamentous strain and resulting pain; therefore, when a person habitually stands with the body in a position of poor posture there is created a lack of normal muscle balance and, consequently, a muscle strain which is translated into pain.

The so-called "carrying posture" is a good example of poor standing position, and is often seen in enteroptotic individuals. The trunk is carried back over the pelvis, the dorsal convexity is increased, and the lumbar spine is hollow or flattened. The abdomen is protuberant or may be scaphoid in type. Backaches are not uncommon in young women with a physiological lateral curvature of the spine associated with a round, hollow back and forward shoulders, and in such patients it is generally easily relieved by adequate exercises.

Other types are seen in women, especially those who present marked hollow backs, with a marked increase in the normal inclination of the pelvis. Such patients often present tenderness along the back muscles over the sacro-iliac joints, and complain of stiffness and a "wooden feeling" in the legs. This is all due to muscle strain and may be relieved by proper support by corsets, reinforced, if necessary, by a belt or extra steels, and in many cases relief is afforded by stretching the tight and contracted heel cords which take part in the general muscular hypertonicity. This stretching may be accomplished only by means of the so-called Shaffer stretching shoe.

Many indefinite backaches which fail to clear up under ordinary treatment are relieved at once by raising the heels of the shoes and by the previously mentioned stretching. High heels are not always the curse that they are made out to be, for by raising the heels the body is tipped back and so relieves the strain on the tense back muscles and hamstrings.

Another source of backache, often persistent, is that due to inequality in the length of the legs. In all patients who are examined for backache the legs should be measured and the degree of trunk displacement should be noted. A short leg is a frequent and often unrecognized cause of backache, and many such cases get early relief by making the short leg longer, or as long as the other one, by means of a lift on the shoe. Any flat foot, or pronated foot, should, of course, be corrected.

Sacro-iliac strain or sprain is a popular diagnosis which means nothing, as a rule; and, while the condition does exist, is not nearly as frequent as one would suppose. Relaxation and displacement of these joints do exist, and actual motion of these joints has been frequently observed, but that all low backaches should be due to so simple a cause is not the luck or "run of the mine" of the practice of medicine.

Simple strains or sprains may be generally easily relieved by strapping, extending it well around to beyond the anterior superior spines on either side, a large felt pad being placed over the hollow of the back and sacrum

Fig. 1. The fracture of the third lumbar vertebra in this patient was the result of a fall from a roof.

and irritable backs so frequently encountered. These can be divided roughly into three classes, namely, (1) poor posture or static backaches; (2) those due to pelvic disease or abnormality in women; (3) those resulting from disease, such as arthritis, tuberculosis, etc., of the vertebrae. These groups will be discussed in the order named and an attempt will be made to bring out the essential points.

Backache from Postural Strain

Under this classification we must also include the cases which are called sacro-iliac strains. Static or postural strains are not the result of trauma, but of the constant muscular strain, and over-use superinduced by an habitual bad position, and may be attributed to definite mechanical and bodily defects. Normally, an individual in the upright position, when at rest, is supposed to carry the weight on his bones and not on his muscles or liga-

*Read before the Nashua, N. H., Medical Society, June 1, 1920.

The strapping should be tight, especially between the trochanter and the crest of the ilium. Manipulation with or without anesthetic will often reduce at one attempt early displacements. Old ones often take care of themselves by gradual bodily readjustment.

Associated with these sacro-iliac strains or displacements there is often a sciatica. In fact, many low dorsal discomforts are manifested early by sciatica, more or less severe, generally clearing up following the adequate treatment of the primary cause. Sciatica by itself is a rare condition.

One other condition seen occasionally, and not so rarely as not to be worthy of mention, is spondylolisthesis, or a slipping forward of the body of the fifth lumbar vertebra on the first sacral body, with a tilting forward and downward of the body of the fifth. This condition may be static or traumatic in origin, and usually leads to great discomfort. The treatment is adequate fixation, either by operation or by a backbrace. Certain severe types of this condition may lead to partial paralysis of the legs. It is a condition described by Sir Arbuthnot Lane as of very common occurrence in coal heavers. An examination of the back in these cases shows, usually, a marked shelf at the top of the sacrum. The fingers can be placed upon the top of the back edge of the first sacral vertebra, and the lumbar spine above seems to have been moved forward as a whole.

There is another type of static posture and backache known as camptocormia or bent back, which has recently been described by Hall.¹ It has also been described by Saliba² under the name of analgic spinal distortion. There is no definite pathology, but the condition is manifestly hysterical, usually following trauma or mental shock, and results in the individual going about with the body flexed at the hips, or displaced laterally. Mental suggestion usually results in an early cure.

When Pelvic Organs Are at Fault

Taking up Class 2, those cases in which the pelvic organs in women are at fault. Graves³ has shown that 76 per cent of 500 cases with retrodisplacement of the uterus had backache. A corrective operation relieved or benefited 86 per cent of 263 cases.

MacFarlane⁴ states that 16 per cent of gynecologic cases complained of backache. The pelvic findings in 159 of these cases comprised chiefly lacerations, retroversion, prolapse, and such inflammatory conditions as adherent appendages and endocervicitis. The incidence of marked nervousness in these 159 patients with backache was about 9.5 per cent, or about equal to the incidence of adherent appendages, and half as frequent as that of prolapse. She thinks that the neurasthenic state predisposes to backache of pelvic origin by lowering the resistance of the central nervous system. The fact that the backache was permanently relieved by appropriate gynecologic treatment has led to the belief that these backaches are caused by the pelvic condition. Uterine or pelvic backache is invariably confined to the sacral or very low lumbar regions.

The common causes of backache in this class fall naturally under the following headings: arthritis, tuberculosis, osteomyelitis, carcinoma, sarcoma, back strain, and sprains, contusions, fractures of the transverse process, or fractures of bodies of the vertebrae.

(1) *Arthritis of the spine.*—This condition is often seen

and is a painful and persistent condition. It has its periods of remission and exacerbation, until such a time as the vertebrae become fused by extension of the process, when the painful joints in the spine no longer exist and the cause of the pain is removed, namely, motion between

Fig. 2. This patient exhibited a fracture of the first lumbar vertebra, causing partial paralysis of one leg, resulting from a fall of twelve feet.

irritable joint surfaces. This condition generally exists with other definite signs of arthritis, may occur spontaneously, or may be present even without symptoms until some strain or trauma stimulates the process and results in great and persistent disability.

Arthritis of the spine is of most frequent occurrence at or after middle age, and is apt to appear in the laboring man as well as the desk worker. It is not uncommon on taking an x-ray of a laborer's back subsequent to an injury to find a considerable degree of hypertrophic

Fig. 3. In this injury the patient fell headlong downstairs, and the fracture dislocation shown in the fourth and fifth cervical vertebrae.

arthritis already present, the process having been aggravated, at least symptomatically, by the accident.

Treatment in these arthritis cases generally resolves

itself into the application of a plaster jacket, a back brace, a canvas corset, any one of which may have to be worn for an indefinite period in order to insure adequate fixation to the spinal joints. A diagnosis of arthritis of the

towards making a diagnosis. Uterine carcinoma may be overlooked, however, and should not be forgotten in searching for a cause. Backache in men may be secondary to prostatic removal, and even if microscopic examination fails to show malignancy, it may exist and cause metastasis in the spine with fatal results. All men with persistent backaches beyond middle age should have an adequate examination of the prostate. It has been my fate to lose two cases in two years from carcinoma of the spine following removal of apparently normal prostates.

Back Strain and Sprain

We will now go back to the question of back injuries as the result of industrial accidents. This class is represented by those patients who have injured their backs by strains from lifting, generally acquired by trying to carry or lift some object much too heavy for them. Many in this category have sudden pain in the back when trying to lift heavy objects. They feel, as they report, something snap or give way in their backs, and are usually able to localize the sore spot very accurately. Generally the pain is in the lumbar region. There may be pain and localized tenderness over the low spinal muscles, usually one-sided, and at times the soreness extends around into the flanks.

It is difficult, at first, to differentiate between muscular and ligamentous tears. I believe, however, that ligamentous tears are of longer duration, and that the soreness and tenderness are deeper seated. Ligamentous tears may be located in the region of the sacro-iliac joints and so may confuse the diagnosis. They do not get well as quickly, and heavy work in the future is apt to produce a recurrence of the soreness and lameness at the same spot.

The term back strain is used advisedly, for any definite classification of these cases is difficult. Many of these cases apparently receive muscle or ligamentous tears involving the fibers of the erector spinae group of muscles, the deep spinal ligaments, or the ligaments which are inserted about the sacrum or sacro-iliac joints. Very few show the typical signs of a true sacro-iliac strain, although it does exist in some cases. As a rule, definite back support is needed for a while.

The mechanics of a crush fracture is generally that of forced flexion of the spine, and the lesion is most commonly located at or about the dorsolumbar junction. The comparative frequency of this type of fracture following injuries to the spine has, in our opinion, been long overlooked, and many cases which have in the past been called "traumatic spines," or "railroad spines," I believe, have been crushed fractures of one or more vertebrae.

A compression fracture of a vertebra is one where the body of the vertebra is crushed or flattened evenly, or more on one side than the other, the injury appearing more often in its anterior portion than the posterior, depending, of course, on the direction of the application of the crushing force. They generally follow severe violence applied through the long axis of the spine, or while the

Fig. 4. This fracture of the third lumbar vertebra resulted from a fall of twelve feet.

spine without an x-ray in a given case is not impossible and at times easy. The back is stiff to bending in any direction, the onset may be sudden or gradual, and the disability is great. The cause may be infectious or occupational. The progress towards recovery is slow, even with good treatment.

(2) *Tuberculosis of the spine.*—This complication is common in children and rather easy of diagnosis by the presence of history, spasm, pain, guarded gait—the so-called military gait—and the presence of a kyphos. In an adult the history is not as suggestive. There may or may not be a kyphos, but it is usually noted if the vertebral destruction has gone on far enough. There are persistent pain in the back and weakness in the legs, even to a beginning paralysis, increased knee jerks, Babinski, and ankle clonus. The iliac fossa should always be examined for the presence of a psoas abscess. The treatment is rest in bed on a frame or in a plaster shell, employing later an adequate jacket or brace treatment. The prognosis in adults is not as good as that in children. It is not an unusual disease in adults and its possibilities should not be forgotten.

(3) *Osteomyelitis of the spine.*—This disorder is not frequent. It may, however, follow after primary osteomyelitis foci or general septic infection. Carcinoma and sarcoma destroy the vertebral bodies in much the same way as tuberculosis. Sarcoma may be primary, and I recall having seen one such case this past

Fig. 5. A fall of fifteen feet resulted in this injury to first and second lumbar vertebrae. Note callus at site of fracture.

winter. Carcinoma generally is secondary to a primary focus in the uterus, breast, or prostate. Occurrence of pain in the back with a kyphosis following the removal of a breast for carcinoma should put one on the right track

Fig. 6. The impact from a fall of seventy feet in this case caused the fracture of the second and third lumbar vertebrae.

spine is forcibly flexed. Falls on the buttocks, shoulder, or back, or landing from a height on the feet, combined with forcible flexion of the spine, are most frequent causes. Heavy objects falling on the patient's back, or being struck in the back by a sharp or heavy object, or being run over and crushed by a wagon, are also adequate causes.

Contusions of the back usually follow a fall or a blow on the back and the resultant injury is usually to the soft parts, although deeper bony structures may be injured. Apart from the bone injuries, however, the prognosis is good, the injury being seldom severe or of long duration.

Fractures of Vertebral Bodies

The level of the first lumbar vertebra is the most common site of this type of injury, probably because of the fact that this is the area of greatest mobility of the spine, and the least guarded by bony protection. The fractures are not limited to one body alone but involve others as well as the first lumbar.

Certain injuries result in a deformity of the back, a kyphos, a backward bowing, or knuckle, as a result of the bony destruction or collapse of the vertebral body. This knuckle or kyphos is not a constant factor, but may result from the fracture of one or more bodies. It is an important diagnostic point to bear in mind, and means only one thing, namely, destruction or distortion of the vertebral body. The kyphos may not make its appearance at once following the injury, but may appear and increase somewhat during the convalescence, especially in the interval when the individual is up and about without proper back support.

The interesting thing about these fracture cases and probably the reason why so many of them are not diagnosed at first is that complaint is made only of a stiff and painful back, with generally some tenderness over the site of the fracture. Very few of the patients have any of the symptoms due to nerve pressure, manifested as loss

freely, and are more limited in side bending than in forward bending. Their disability at first is generally complete, but as time goes on they are able to be up and about but not able to do heavy work.

In regard to the graver symptoms accompanying these

Fig. 8. Same case as that shown in Figure 7. The fracture of the first lumbar vertebra was complicated with a pre-existent hypertrophic arthritis. This condition was exhibited three years after the accident.

fractures, certain of the cases show definite signs of cord injury, manifested by loss of sensation in one or both legs, not complete, and more or less paralysis either early or late. Some of the cases which showed early loss of muscular power recovered it wholly, while others have suffered permanent damage to the cord from pressure of the injured vertebra.

The treatment in all these cases should be early and adequate fixation of the spine, in a plaster jacket at first, and later by a back brace. The whole period of treatment may probably cover several years. The question of operation on the spine designed to furnish support to the crushed vertebrae has been considered and has been done in some cases with the view of cutting down the period of convalescence and disability.

The conditions causing these injuries are clear, a fall from varying heights and landing on the back, the injury due to direct violence. Now, direct violence may produce many results, such as fracture of the vertebral bodies, or fracture of a transverse body, laminae, a spinous process, rupture of anterior or posterior spinal ligaments, as well as even rupture of the ligamentous nucha or intraspinal ligament. Contusions involving both deep and superficial muscles and ligaments are common and injuries to the tendinous insertions of the spinal muscles and ligaments in the region of the sacrum are frequent. Over-extension or forced hyperextension of the spine may produce injury to the anterior spinal ligaments; while forced flexion may produce not only a compression fracture but ligamentous rupture as well.

The predilection of the sacro-iliac ligaments to become injured is well-known, and generally misinterpreted. The necessity for clearly localizing the anatomical forces of the distribution of pain and other signs and symptoms is obvious, and an analysis of the method of production is essential to a correct interpretation of the condition, without which one may go far astray. An x-ray is always an essential, even purely on a negative basis.

Many of these cases suffer from sciatica as a result of

Fig. 7. In this fracture injury there is exhibited a hypertrophic arthritis which was pre-existent to the accident. Its existence in such cases may lead to confusion of diagnosis. (See Fig. 8.)

of sensation, paralysis of the legs, or incontinence of the bladder and rectum. This lack of nerve involvement in probably due to the fact that the spinal cord ends at about the level of the first lumbar vertebra, the point of greatest frequency of fracture, and so escapes injury.

In practically all cases of this injury the complaint is of a stiff, lame, and painful back. They cannot bend

their injury, clearly secondary but due to the accident. Sciatica may follow direct injury, or falls on the hips, back, or buttocks, as well as ligamentous and muscle strain due to lifting. It is due probably to compression of the nerve trunk somewhere along its course or to pressure on the nerve ends at its origin. In a certain number of cases, definite areas of anesthesia are manifest along the distribution of the external cutaneous and muscular cutaneous nerves.

Another common condition complicating these back injuries is hypertrophic arthritis, generally quiescent and

pre-existent to the injury. The accident usually lights the condition up and so aggravates it. Without this complication the disability period might be short; with it, the period is indefinitely lengthened and may be controlled only by careful and skillful treatment. The presence of hypertrophic arthritis in a spine which presents a crush fracture of one or more vertebral bodies may lead to confusion in that the vertebral bodies may be so altered by the arthritic disease as to resemble a fracture, and one cannot be too constantly on his guard in the interpretation of such x-ray plates.

CHRONIC CARBON MONOXID POISONING—ITS IMMEDIATE AND SUBSEQUENT MANIFESTATIONS

BY GEORGINE LUDEN, M.D., PH.D., FIRST ASSISTANT IN PATHOLOGICAL RESEARCH, MAYO CLINIC, ROCHESTER, MINN.

FEW physicians have the opportunity of studying the effects of chronic carbon monoxid poisoning on themselves and of making uninterrupted observations during twelve months on three friends similarly affected. It has been my good fortune to gather subjective and objective data in this way. Sensations recorded by one's own tissues furnish a clinical picture of singular vividness. My experience, therefore, proved as instructive as it was unpleasant.

McGurn gives a graphic account of the symptoms which may be produced by prolonged inhalation of small amounts of carbon monoxid (CO); McCombs has published observations made on one thousand cases of acute gas poisoning. These two articles only came to my knowledge three weeks after positive Katyama tests, specific for carbon monoxid (Matthews) had furnished conclusive evidence of the presence of "coal gas" in my house. The symptoms described by McGurn and McCombs were found to coincide with those which I had observed in myself and of which I had kept a written record because I was unable to explain their cause.

Signs Often Misinterpreted

Chronic carbon monoxid poisoning will, without doubt, shortly be recognized as an important feature of modern life. At present the toxicity, imperceptibility, and ubiquity of the treacherous gas fail to be sufficiently appreciated by the majority of physicians and by the general public. Its properties have been studied chiefly in connection with scientific research (Haldane, Henderson), industrial problems (Teague) and the construction of public means of transportation (Henderson and Haggard).

The manifestations of chronic carbon monoxid poisoning are overlooked or misinterpreted in nine cases out of ten, because they appear to be the result of any number of other factors. The reason for this is twofold: the sources of CO production escape notice because of their apparent insignificance; the symptoms produced can be numerous and diverse, and they are apt to be attributed to other causes. The layman ascribes the effect of minor degrees of poisoning to overexertion, the weather, a mere cold, or "rheumatism"; the physician is likely to suspect even the more severe symptoms of being the result of "a touch of influenza," dietary indiscretions, neurasthenia, or hysteria. The diversity of the symptoms produced in chronic carbon monoxid poisoning may be explained by (1) the amount of gas inhaled, (2) the duration of exposure, and

(3) the relative efficiency of the endocrine glands of the victim in a given case.

Toxicity of Carbon Monoxid

Carbon monoxid kills in a dilution of 1:2,000 (Albaugh); it produced severe clinical symptoms on prolonged inhalation in a dilution of 1:250,000 (McGurn). Dilutions expressed in figures only convey little meaning. It is worth remembering, therefore, that in order to obtain a dilution of 1:2,000 a small glass of whisky (10 cc.) must be mixed with the content of the familiar five gallon gasoline can; and that the higher dilution—1:250,000—represents the content of the same small glass diluted with 625 gallons, that is, the content of the standard city sprinkling cart (Fig. 1). Yandell Henderson and his collaborators tested the effects of a dilution of 4:10,000 on themselves; no immediate symptoms were produced by this concentration, which represents one hundred of the small glasses diluted with the content of the city sprinkling cart. They question the accuracy of McGurn's estimate of a dilution of 1:250,000.* Their experiments, however, constitute an example of scientific heroism in view of the treacherous properties of carbon monoxid and the possible after-effects of its inhalation.

Imperceptibility of the Gas

It is a common error to assume that "coal gas" cannot be present unless it is perceptible by the sense of smell. No conception could be fraught with more danger. Carbon monoxid is as odorless as well as a colorless gas and slightly heavier than air; its presence would never be detected were it not for the addition of other compounds with which it is usually associated. McGurn states emphatically that "*grave danger* always exists when coal or illuminating gas is inhaled in quantities sufficient to be detected by the normal sense of smell." During the entire period of the nine weeks in which severe symptoms were produced by the inhalation of carbon monoxid in my house not the faintest trace of "furnace smell" was observed by any one.

Ubiquitous in Modern Life

Carbon monoxid is produced in varying amounts wherever the usual varieties of fuel—coal, wood, petroleum, or gasoline—are subjected to incomplete combustion. It is universally conceded that only from 25 to 40 per cent, or at the most 60 per cent, of the energy stored in fuel is transformed into another form of energy by combus-

*Personal communication.

tion engines, including furnaces; the remainder is converted into by-products. All fuel contains the carbon atom, which, in the presence of an oxygen deficit, may lead to the production of the deadly compound, carbon monoxid.

Wood, which is generally believed to be incapable of becoming a source of coal gas, is eminently capable of producing it. "Illuminating gas made from wood may contain as much as 60 per cent of carbon monoxid" (Da Costa:Mohler).

Chimney smoke is usually looked upon merely as an economic waste and a public nuisance. McGurn was able to prove in Cases 10 and 13 that soft coal smoke from a nearby chimney, which blew into an apartment for a few hours daily during a couple of months, caused very severe symptoms of chronic coal gas poisoning. The details given by McGurn are most instructive and should be read by every physician. Acute carbon monoxid poisoning by chimney smoke in seventy-three of 125 workers in a men's clothes manufacturing establishment has been reported by Harris.

Natural gas is responsible for many deaths yearly. It contains 90 per cent methane (CH_4)—that is the so-called marsh-gas or sewer-gas—and a mixture of other gases in varying proportions. Mellor attributes its harmful properties to "dilution of the oxygen." Its action, therefore, somewhat resembles that of carbon monoxid, which reduces the transportation of oxygen in the body. Inhalation of both gases results in an oxygen deficit for the organism. Natural gas is used extensively in Indiana, Pennsylvania, Ohio, West Virginia, New York, and California; to a considerable extent in Kansas and Kentucky; and to a lesser extent in Utah, Colorado, Illinois, Missouri, and Texas. In two nonfatal cases which came under my observation the after-symptoms closely resembled those of chronic carbon monoxid poisoning. The patients had never

Fig. 1. E. Dilution 1:2,000 in which carbon monoxid kills (Albaugh). Dilution 1:1,250,000 in which carbon monoxid does serious harm (McGurn).

Illuminating gas made from coal contains from 5 to 10 per cent carbon monoxid; water gas, "so largely made for illuminating and cooking purposes, contains approximately 30 per cent" (DaCosta:Mohler). Henderson has recently pointed out that 20 per cent of the toxicity of illuminating gas is caused by other compounds as poisonous as carbon monoxid. Death occurs after the blood is charged with 85 per cent of pure carbon monoxid made from formic acid; but a saturation of the blood with only 65 per cent of illuminating gas proves unavoidably fatal. The United States Bureau of Mines has shown very recently that three out of five types of gas tubing in common use are dangerous and unreliable, while two out of four varieties of gas tubing connections are equally unsatisfactory, leaks being frequent (Winters). Gas is used daily for a thousand purposes in our homes, laboratories,

and factories. Few people attach any significance to the "faint smell of gas," which is associated with practically all gas appliances; yet this faint odor heralds the minute traces which are probably the most common cause of chronic carbon monoxid poisoning.

Sources of Carbon Monoxid Poisoning

Apart from defective gas fittings, tiny rifts in furnace pots, and the prolonged inhalation of small amounts of auto-exhaust gas, consideration must be given to two sources of carbon monoxid production of which the danger is not real-

Fig. 2. (FI). Chart of blood constituents of F. F. G. from September 18, 1919, to March 18, 1920.*

ized by the average householder, namely, the iron "breaching" connecting furnace and flue and the ordinary lime-mortar used in the old houses to make the flues air-tight. The iron breaching is corroded by the combustion fumes and becomes porous like old India-rubber. Ordinary lime-mortar is also disintegrated by heat and combustion fumes; its use has been condemned by the Building Code of the National Board of Fire Underwriters (1915), on account of "fire-hazard," but it may be found in many old houses. It is obvious that fire hazard implies the escape of fumes. Both factors probably played a part, albeit a minor one, in my experiences with carbon monoxid. My brick house was built about forty years ago and, in common with most people, I was entirely unaware of the danger of a porous iron breaching.

The cause of carbon monoxid production in my house is worth considering because it may easily be duplicated in many American homes. Two furnaces, both situated in the basement, were connected with the same flue. The larger furnace—hot water system—controlled the central heating; the smaller one furnished the hot water supply. During the damp, chilly days of September, 1919, the big furnace was fired in the daytime only with old wood of which we wanted to dispose; the small furnace, heated with coal, burned night and day. All flues cooled off at night. The additional loss of heat caused by the "going out" of the big furnace failed to be compensated by the warmth of the small furnace. A down draught, produced by the cold heavier air at the top of the flue, forced the

*Key to Figures 2, 3, 4, 5 and 6: Reading from top of chart to bottom. B.C. Blood catalase; L.D. Lymphoid defence, percentage of small and large lymphocytes; B.I. Bloor I cholesterol (heavy line). Bloor I cholesterol per 100 cc. of whole blood; 100 mg. or 0.1 blood sugar; 100 per cent hemoglobin, but 10,000 leukocytes.

combustion gases into the house. Similar conditions obtain when fires are lighted for the first time in autumn and the flues are cold; they may be produced in any single flue intended to carry off the smoke furnished by two fires

Fig. 3. (AVI). Chart of blood constituents of G. L. from August 2, 1919, to December 19, 1919.**

of unequal intensity, for the less warm column of air above the smaller fire fails to warm parts of the flue sufficiently and a down draught results. This is not realized by the majority of people and is sometimes overlooked even by architects and engineers.

First Manifestations Deceptive

The symptoms produced by carbon monoxid in my home must be described in detail because they were completely misinterpreted and attributed by myself and several other physicians to factors in no way responsible, but which we had a right to suspect to be the cause of these symptoms, because there was nothing to suggest the presence of a toxic gas.

An unmarried woman, aged thirty-three, living at my house had apparently recovered from a moderately severe attack of influenza. In previous years she had undergone several operations, including a Kelly's fixation of the left kidney. She is tall and delicate and the type of those whose enthusiasm and energy are apt to overtax their strength. She had been very active arranging the decorations for the wedding of a friend which had taken place at my house. Two days later (Saturday) she was seized with attacks of intense abdominal pain accompanied by visible spasms of the lumbar and abdominal muscles. Overexertion resulting in displacement of the kidney naturally suggested itself as the cause of the symptoms; the attacks resembled Dietl's crises. She was kept under opiates during the following day, the Clinic being closed. A cystoscopic examination, roentgenogram, pyelogram, and functional test, on Monday morning, failed to reveal any abnormality. The patient did not appear to be unusually exhausted after the examination. She was taken back to my house and rested comfortably on Tuesday. At eleven o'clock Wednesday evening she suddenly developed alarming symptoms of collapse: the pulse disappeared, breathing stopped, to be resumed with difficulty on admonition. Her face became haggard, the eyes assumed the "broken" look which usually heralds death (*facies Hippocrates*). The sudden onset of the symptoms seemed inexplicable. I succeeded in making her swallow some brandy and black coffee (strychnin injections appeared contra-indicated because of the previous muscle spasms) and summoned a senior colleague. When he arrived, ten minutes later, pulse and respiration had improved considerably, but the patient was suffering from a severe shivering attack without demonstrable cause: the temperature had been normal

all day. The patient called our attention to the peculiar behavior of her hands; they were rigid, the fingers were fully extended, but they relaxed in a few minutes. A reaction then set in, and notwithstanding the patient's manifest efforts at self-control, tears began to roll down her face. My colleague pronounced the syndrome "the best case of shock he had ever seen," but was no more able than I had been to account for the occurrence of "shock" more than sixty hours after a cystoscopic examination and following twenty-four hours of comparative well being.

After the reaction the patient's condition was satisfactory, but during the remainder of the night she had several other less severe attacks of syncope. She had chaffingly accused me of over-anxiety at first, but towards morning she admitted dreading these attacks; she feared that she might not have enough strength to go on breathing, it required such an effort. In view of her previous cheerful attitude this admission gave cause for apprehension. It occurred to me to try injections of camphorated oil. During my studies in Europe I had been taught to look upon camphor as a stimulant of the respiratory centrum and these mysterious attacks of syncope seemed to be somehow associated with inhibition of respiration. Hypodermics of 0.1 gm. of camphor in sterile oil gave immediate relief, but their effect lasted for only about two hours. The possibility of an occult adrenal or intraperitoneal hemorrhage suggested itself, in which case camphor would be contra-indicated. Hemolytic *Streptococci* had been isolated in many cases of influenza in which adrenal hemorrhages had been found at necropsy. The patient had had influenza and the severest pains were located in the lumbar region. At my request an eminent surgeon examined the patient, who at this time did not present the picture of severe illness as the camphor stimulation was still effective. He decided that internal hemorrhages might safely be excluded; the symptoms appeared to him to be nothing but a severe nervous reaction.

During the following weeks—September 15 to October 25—the patient's condition showed little change. Intense abdominal pains, visible spasms of lumbar and abdominal muscles, sudden attacks of syncope, and chills without rise of temperature, alternated with periods of comparative well being. The attacks came for no demonstrable reason, generally without warning, but, further confusing the problem, mostly between seven and nine in the evening. Minor symptoms developed: headaches located behind the eyes, but the patient had suffered from headaches for years; occasional, if rare attacks of nausea; obstinate constipation; irritation of the bladder with difficulties in micturition; the bladder symptoms were ascribed to the elimination of the camphor, but were also observed when no camphor had been given. The temperature was normal or subnormal with an occasional evening rise; this, too, had frequently been observed in previous years. The heart sounds were normal. The pulse was of a good quality, on the whole regular, 68 to 72 beats to the minute. At intervals, however, the pulse showed irregularities of a puzzling character: series of good strong beats alternated with series of small, "flat" beats that were scarcely perceptible, but without acceleration. The electro-cardiograph failed to reveal these abnormalities, although they could be felt at the wrist. Urinalysis and blood counts showed nothing abnormal: the erythrocytes were 4,500,000 to 5,000,000, which seemed high considering the general debility of the patient; the hemoglobin was 70 to 75 per cent; the leukocytes 6,000 to 10,000. The blood pressure was low: systolic 70 to 80, diastolic 60 to 70; the pulse pressure often did not exceed 10 mm., observations being made daily at the same hour and frequently repeated at different times of the day with the Tycos sphygmomanometer. The blood sugar was very low, 0.05 to 0.06 gm. per 100 cc. of blood; the blood cholesterol values were high on the whole, 130 to 155 mg. per 100 cc. of whole blood (Fig. 2).

Tuberculosis of the parietal peritoneum (Quervain) was suspected, but the absence of tympanitis made the diagnosis doubtful. The patient was cheerful, even inclined to be over-active when she was free from the more severe symptoms, but slight exertion produced marked exhaustion. She was kept in bed on account of this great fatigability.

The total lack of demonstrable findings seemed to jus-

**G.L.'s and H.H.G.'s blood sugar dropped to 0.04 mg. October 30. Both persons had been in the carbon-monoxid laden cellar repeatedly between October 25 and 30.

tify the diagnosis "neurasthenia," although I could not endorse this diagnosis; it has always seemed to me a mere admission of ignorance concerning the cause of symptoms, which, in nine cases out of ten, adds mental suffering to the physical distress of the patient.^{*} There was, moreover, in the entire syndrome a vague, intangible element of danger for which I could not account, but of which, as I watched the patient day and night, I could not help being acutely conscious, although others who only saw her at intervals for a short time were naturally skeptical.

During this entire period of five weeks my own physical condition began to alarm my friends. I looked and felt wretched. However, lack of sleep (the attacks of syncope often came during the night), anxiety about my patient—an only child entrusted to me by her mother whom circumstances prevented from coming—and this undefined consciousness of danger which kept me on the alert every minute, seemed more than sufficient to explain my weariness. In addition I was trying to write a thesis against a given time. All my subjective symptoms, facial neuralgia (which had troubled me since I had recurrent fever many years ago), vague aches and pains, breathlessness, and an occasional attack of nausea, were therefore attributed to mere fatigue (Fig. 3).

Symptoms Still Unexplained

I kept a record of these symptoms for future reference in connection with serial observations on my blood cholesterol, which I had been making for five years, but otherwise I paid little attention to them. One peculiar occurrence must be mentioned: I repeatedly awoke suddenly on account of the inexplicable and uncomfortable behavior of my heart: it seemed to be turning somersaults. Whenever this happened I concluded that my patient had called me (her room was next to mine), for I invariably found her fighting for breath, on the verge of syncope. We jokingly decided that she must send a mental *S. O. S.* when breathing became difficult. Her throat had often felt sore, "raw" during these weeks. October 25 she developed slight symptoms of laryngitis and bronchitis; steam and benzoin compound were used to relieve these symptoms. That evening she complained for the first time about giddiness when sitting up in bed; she was very pale and her pupils were dilated. I was sitting on the edge of her bed when she remarked that I had suddenly "changed color" very markedly. I had to admit that I, too, felt giddy. She then suggested that the bezoin fumes, by accumulating in the corner where her bed stood, might be responsible and, in order to test this theory, I went into the middle of the room. Here I noticed that my giddiness increased instead of decreased, which made me suspect for the first time the presence of carbon monoxid, because the heavy gas does not rise unless wafted upwards by some current of warm air, and columns of gas-laden and pure air will, consequently, be found side by side in the same room. The most probable explanation appeared to be a "burst of gas," such as is often produced by a small explosion of the coal in furnaces. I went into the cellar to investigate. There was no odor of furnace gas. The large furnace supplying the hot water heating system was out; the small furnace taking care of our hot water supply seemed to burn half-heartedly. I opened all the dampers and, as a precaution, all the windows in the house. As a matter of precaution also I gave the patient and her nurse a big cup of black coffee and took coffee my-

be overheated. This time the air in the cellar was difficult to breathe, but there was no odor. I broke a window pane and opened the outer cellar door to create a draught. When I began to ascend the second flight of stairs I no-

Fig. 4. (CII). Chart of blood constituents of Mrs. H. H. C. from 17, 1919, to January 9, 1920.**

self. Three-quarters of an hour later I went to the cellar again to close the dampers lest the hot water pipes should ticed that I was swaying; my legs felt as if they did not belong to me. I lurched into the patient's room and my pulse was observed to show the peculiar irregular "flatting" and my face the greenish pallor with vivid red spots on the cheek bones and dark red lower lip which I had noticed and been unable to explain in my patient. My pupils were widely dilated; my chest felt as if it were made of concrete; my heart seemed to be beating with an effort of which I was conscious; in other words, short of syncope. I was duplicating the syndrome which had baffled interpretation. A camphor injection speedily removed the feeling of weight in my chest and I was seized with an attack of shivering which no exertion of will power could control. The fact was now recalled that friends, husband and wife, who had dined with me that evening had shown symptoms belonging to carbon monoxid poisoning—he had been overcome with drowsiness while I read a story to them, and the wife had complained of a bad headache. Both had ascribed their lassitude to fatigue and suggested that they might be getting influenza, the disease being prevalent at the time. I also remembered noticing that my patient's nurse did not seem well that evening, her cheeks being a very vivid red. These two facts showed that there must have been carbon monoxid in the house several hours before I had inhaled a large amount of it in the cellar. This was connected with the fact that the attacks of shivering which usually developed in my patient between seven and nine p. m. might bear a relation to the "going out" of the big furnace at that time, when the resulting down draught was likely to force a greater amount of gas into the house. Consequently the big furnace was kept burning night and day. This precaution, however, did not eliminate the production of gas, and thorough cleaning of furnaces and flue proved no more efficacious. Between October 25 and 30 my patient and I had several attacks of dyspnea and shivering. Although there was now no doubt as to the cause of these symptoms, others still denied that these symptoms were produced by carbon monoxid, until Katayama tests made on the blood of the patient, the nurse (who, not having been exposed as long did not show any severe symptoms) and

*A little girl cousin of mine, who died at the age of nineteen from typical Addisonia, although bronzing remained confined to circumscript areas, suffered acutely for five years through this diagnosis, and the stigma of "faking" which it represents to the lay mind. She was the pluckiest, most unselfish, and most cheerful patient I have met.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

THE WAR AGAINST THE RAT

THE "serious, even though not alarming bubonic plague situation in the Southern States,"—to quote from resolutions of the Conference of State and Territorial Health Officers held at Galveston last summer,—has led to an active interest in the anti-rat campaign in seaboard states as far north as Massachusetts. India has been the primary focus of plague for the last twenty years; but secondary foci exist in the Dutch East Indies, Indo-China, Egypt, Senegal, and certain South American countries. Serious outbreaks at various Mediterranean ports, and at Vera Cruz, in 1920 brought the menace clearly home to western Europe and the United States, respectively.

The rat richly deserves attention on its own account and not merely as the principal reservoir of the germ of plague. Creel¹ estimates that in the ordinary American or European city the rat population is just about equal to the human population, while in rural districts our rodent cousins greatly outnumber us. The upkeep of the rat is estimated to cost at least a half a cent a day in the United States and in Great Britain; so that we may conservatively conclude that as a nation we are paying a tribute of two dollars per person per year for the maintenance of these highly undesirable aliens in our midst.

It is the possibility of plague infection, however, that makes the situation so immediately critical at the present moment; and the first duty urged upon the health authorities of seaboard towns is the determination of the presence or absence of plague infection in the existing rodent population. By means of a carefully conducted rat survey it is possible to know with a fair degree of certainty whether or not rodent plague has been introduced. It is reasonable to believe that plague always exists among rats for some time before the infection is transmitted to human beings. The Public Health Service has recently published a very valuable discussion of this problem² in which it is suggested that a fair basis of judgment requires the examination of 100 rats per 1,000 human population. Trapping is the only method to be considered in obtaining specimens for laboratory examination, and the cost of capturing and examination is likely to average about one dollar per rat, or ten cents per person in the population, on the basis estimated above.

The most vigorous anti-rat measures should, of course, be immediately instituted in the neighborhoods where infected rodents, and still more where human cases, have been found. Campaigns along this line have been economically conducted in Manila and New Orleans,³ and in Japan the rats have sometimes been first imprisoned in the infected area by sinking a barrier of corrugated iron into the ground surrounding it.

The efficacy of various traps and poisons has been admirably discussed in a recent contribution by Dewberry⁴; but sporadic attempts at the destruction of rodents by trapping and poisoning are of little value, except as applied to the rats in such specially infected areas as those described above. The real remedy is the rat-proofing of buildings and the enforcement of such measures of municipal cleanness as will radically limit the extramural sources of rodent food supply.

The recent bulletin of the United States Public Health Service to which reference has been made above⁵ contains a statement of the necessity of rat proofing and an estimate of the economic gain from such measures and gives an admirable model rat-proofing ordinance which is essentially suitable to any urban community. It provides for the division of all buildings into two classes, Class A including restaurants, hotels, slaughter houses, bakeries, and all other places where foods are handled or stored on a large scale, while Class B includes ordinary dwelling and other buildings except stables (which are separately treated). Buildings of Class B must be rat-proofed by the laying of a three-inch concrete floor, hermetically sealed to six-inch walls of concrete or brick or stone, laid in mortar extending two feet downward and twelve inches upward from the floor. Stables are to be similarly treated, though the floor must be six inches thick and many other structural details are specified.

Buildings of Class B may be rat-proofed by raising them upon pillars or underpinnings eighteen inches above the ground or by constructing at the margin of the ground area of the building a six-inch sustaining wall of concrete, or brick or stone laid in mortar, extending two feet below the ground level and meeting the floor of the building closely. Other sections deal in careful detail with the handling of rubbish and the replacement of planking and plank walks, the construction of cellars and the like.

Such measures cannot exterminate the rat; but they should so reduce the number of the rodent population as to eliminate practical danger of the spread of bubonic plague and cut down to a negligible amount the economic loss due to rat depredations.

MAKING MICHIGAN FIRST IN HEALTH

BY R. M. OLIN, M.D., COMMISSIONER OF HEALTH, LANSING, MICH.

NO MAN, I believe, can be a good public health man and have anything of the pessimist in his make-up. He must be an optimist through and through if he is to succeed in public health work; and the more time one devotes to public health duties, the more must he cultivate and acquire the spirit of optimism and patience. The ideal public health worker should have the combined qualities which make a great detective, a beloved family physician, a scientist, a business administrator,—and something of the wit who said: "The surest road to happiness is paved with imagination, and the best means of locomotion is to kid yourself along."

Personally, I like frequently to recall the motto of Will Levington Comfort, one time Detroit elevator boy who by sheer force of will and perseverance rose to what he is today. Comfort lives by the following creed, a creed that many persons would do well to include in their daily life: "Like it all wonderfully well; getting the warm laugh on it all, and believing firmly that the best possible thing that can happen is the thing that happens next."

defined lines of work in every health department, but elastic in structure to conform to changing needs.

There may have been a time in the peaceful past when a state health executive could write an article on the functions and accomplishments of his department and look forward with a sense of satisfaction to reading that article several months hence and finding it still applicable; but that time, if it ever existed, has long since passed. In public health work today, as in our present industrial organizations, events are crowding fast, developments are unfolding too swiftly, to permit of any permanency of record. What we write today we revise tomorrow.

We are finding that true daily at the Michigan Department of Health. Where for years we had a State Board of Health with the secretary acting as executive officer, we now have a State Department of Health with a commissioner, a deputy commissioner and an Advisory Council of Health. Our last legislature brought about that reorganization. Keeping pace with this change, the entire work of the department has been systematized and correlated into bureaus, based, of course, upon the well

The skeleton outline of the Michigan Department of Health organization is simple. There is no complicated overhead wound with red tape to impede quick action. We realize that the very fact that we are a relatively small and compact organization is in our favor. You can get quick results with a unified group of eighty-five persons such as we have. If the growth of the next three years keeps pace with that of the last three, and every indication points that way, we will soon face the problem of getting the same quick action with a more complicated organization; but I believe that we have the basic structure that can carry indefinite expansion.

Our seven bureaus are mutually inclusive, never exclusive. There is, as always must be, the closest cooperation.

The Bureau of Sanitary Engineering, headed by Maj. E. D. Rich, is our senior bureau and it handles all problems of sanitation, water supplies, sewage disposal, garbage disposal, and the hundreds of requests from the municipalities for everything from expert consultation to assistance in cleaning the back yard. At present we are doing some special work in stream pollution. The fact that Michigan is surrounded by lakes and crossed by numerous rivers complicates rather than solves our sanitary problems. The thousands of nonresident fishing licenses issued yearly attest the popularity of Michigan waters. Michigan's summer resort industry, which attracts vacationists who spend \$100,000,000 each season, and the state's fisheries, with earnings based at \$25,000,000 yearly, will be destroyed unless adequate sanitary measures are taken to protect the fish life. Nearly all the industrial wastes, such as oil from automobile factories, milk washings from condensaries and dairies and beet sugar refuse, are detrimental to the fish, and the proper disposal of these wastes presents a difficult problem which we are trying to solve.

To the sanitarian, resorts too often spell vacation typhoid. They do in Michigan, and one of the most interesting developments in state health work is our attempt to meet the resort problem with a "laboratory on wheels," as the newspapers chose to call it. A completely equipped motor truck laboratory ready to test water samples, milk samples, and inspect waste disposal, was sent up the resort-dotted coast of the state.

This laboratory visited fifty-nine resorts in the seven weeks it was on the road, with the unanimous support of the hotel men and resort owners. So encouraging were the results obtained that an additional truck will be put in the field next season. It helps business while it safeguards health,—a working combination not to be scorned by any health department that wants results. The motorized laboratory was the combined effort of the Bureau of Engineering and the Bureau of Laboratories, with a close connection with the Bureau of Communicable Diseases. It was also a most effective exponent of the Bureau of Education because the truck visited the state university and the state normal college at the beginning of its trip, giving to the summer school students a practical demonstration of public health work. The task of the motorized laboratory is far from finished. With the closing of the resorts came the opening of the schools and the important question of pre-school and school inspections to detect disease carriers, and the truck is serving as the center of the "swabbing parties."

Michigan has a big problem to face in its diphtheria

Michigan's "Laboratory on Wheels" safeguards not only health, by aiding in the prevention of vacation typhoid, but protects the summer resort industry.

death rate, and active measures have been under way for several months for a concerted attack.

In one of our regular bulletins sent to all doctors and health officers in the state attention was called to the seriousness of the situation, and pre-school inspection for the detection of carriers was urged. The response was overwhelming. From the opening of the schools up to the first of November 35,000 swabs have been sent out by our laboratories to health officers and physicians to be used in taking cultures from the throats of school children. In addition to this, 10,000 cultures have been taken by the personnel of the department. The health officers, doctors, nurses, and school men of the state are offering splendid cooperation, and we have been obliged to put on a night shift in the laboratory to meet the emergency. One incident of the school work was the visit of the traveling laboratory and a corps of five technicians to St. Clair county, where the throats of 6,500 school children were swabbed and about fifty carriers detected. The chief value of swabbing, we grant, lies in the education it brings to the community. When we reach the point where we can Schick and actively immunize, the solution of the diphtheria problem will be attainable. But, though we have used the Schick test in several schools of the state, we have not yet reached the stage of general use and, in the meantime, the school that has been swabbed—twenty-seven localities have been visited in Michigan this fall—is the school that is alive to the fact that the throat is an important part of the anatomy.

Schick Test State Wards

An interesting example of the working out of the Schick test is evidenced at our Michigan Home and Training School at Lapeer, where, under the supervision of Dr. C. C. Young, director of laboratories, 1,800 patients and employees were tested and 243 Schick positives were found. This eliminated 1,557 persons from prophylactic treatment in case of an outbreak of diphtheria and saved the institution \$7,000 per year formerly expended for anti-toxin.

The outstanding features at present in our Bureau of Communicable Diseases, under the direction of Dr. W. J. V. Deacon, are the traveling clinic and the work in school inspection.

When the Michigan Department of Health took over the tuberculosis clinic from the Michigan Anti-Tuberculosis Society it was a definitely specialized clinic. We have changed that. First, we added a children's specialist to reach the pre-tuberculous group of children, and we have succeeded in doubling the percentage of children usually examined in a tuberculosis clinic. We have now added a venereal disease clinic and in January we introduced a child welfare unit. We have, in addition to enlarging the clinic staff, changed the emphasis of our publicity, urging general physical examinations for everyone in the community, whether there is a definite suspicion of tuberculosis or not.

I believe in a broad, many sided attack upon any public health problem, and one of the most telling weapons is a traveling clinic. There is no better concrete service that a state department can offer the smaller communities, particularly, than to make available the expert medical service that gives our city children the advantage over their country brothers and sisters.

Broaden Venereal Disease Work

The most rapid and spectacular growth in the whole department can probably be attributed to the Bureau of Venereal Diseases. A war measure first, it is now a

A motor truck is completely equipped as a laboratory ready to test water samples, milk samples, and to inspect waste disposal. (1) Cases for miscellaneous light articles. (2) Dome lights, two. (3) Copper water tank 20 gal. capacity. (4) Hose from water tank to sink. (5) Sink. Folds into space at right. (6) Sink hinges. (7) Sink outlet. Hose through floor to ground. (8) Pressure cooker used as autoclav. (9) Kerosene stove. (10) Oven for dry heat sterilizer. (11) Dishpan. (12) Wheel housing. (13) Removable door from sink cupboard. (14) Incubator, Eberbach, 12"x12"x14" inside dimensions. (15) Cleats for extra seat. Capacity of seats, four people. (16) Folding work bench. (17) Cupboard for sterilizer and other articles. (18-19-20) Stacks of drawers. (21) Folding microscope. (22) Microscope lamp. (23) Gasoline bunsen burner. (24) Rear door.

definite and indispensable part of our state health organization. Michigan has as stringent and effective a venereal disease control law as any state in the Union. The whole problem, from our viewpoint, is one of public health, and we have had the practically united support of the medical and nursing professions, the druggists, the social workers, and the people generally of the state. Michigan can boast of the largest legislative appropriation of any of the states—\$300,000 for two years. Dr. G. M. Byington directs the activities of this Bureau.

We have hospitalized more than 2,000 cases, men and women, and we are now treating over 1,800 cases a month in the ten clinics throughout the state. Naturally, with the increasing number of clinics, hospitalization is being cut down. In our hospital work we have not been content with merely giving medical treatment, but by a system of state supervision we have given social after-care to the discharged patients, just as the up to date hospital gives after-care—to insure the permanency of the medical treatment. The cooperation of the druggists of the state in reporting prescriptions filled has been one of the most encouraging features of our campaign. More than 88 per cent of the druggists are reporting monthly.

In Michigan all matters pertaining to embalming are by law brought under State Department of Health control. We have a special bureau that handles that phase of public health work, examining and licensing all embalmers and giving general supervision.

A good deal of interest centers around our Bureau of Education. I believe that public health education is as vitally important a line of work as any followed out in the State Department, and to get it done effectively and with any unity it must be centralized.

The old method of each bureau carrying education as a side line does not make for a coordinated state program. Consequently, we clear all our education and publicity activities through a bureau. Call it an ideal type of organization, if you like. It works in Michigan, and we are well aware that the reason it works is because of

DIETARY HYGIENE AS TAUGHT BY MUSEUM METHODS

BY MARY GREIG, DEPARTMENT OF PUBLIC HEALTH, AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK CITY

THE general problem of malnutrition among school children is receiving the serious attention of the various departments of education in connection with the work of the school lunch service.

It has been felt in New York City that the provision of lunches for the children is not sufficient by itself to establish proper dietary habits. Only 9 per cent of the children take the lunches and, if a child eats the school lunch regularly, he obtains only 5 per cent of his yearly total of meals in this way. Because of this fact, as well as for other reasons, it has been realized that the school lunch to be effective must be supplemented by definite instruction in dietary hygiene in the classroom.

The normal child possesses a natural appetite for wholesome, simple foods which enables him to eat with relish dishes that seem insipid to the perverted tastes of many adults. The purpose of dietary education is to transform this rational appetite into habits of correct eating which will persist through adult life.

With this end in view, Dr. Gustave Straubenmüller, associate superintendent of schools of New York City, sent a request for teaching material on dietary hygiene to the American Museum of Natural History. To meet this demand we have prepared a traveling loan exhibit under the direction of Professor C.-E. A. Winslow, curator of the Department of Public Health of the Museum.

This exhibit consists of a set of sixteen wax models of foods suitable for a child between ten and thirteen years of age (Figs. I and II), a set of colored wooden blocks which illustrate the composition of six common foods, and eight wall charts.

These food models can be used in several different ways to teach the essential principles of dietary hygiene. They can be used to give the child the idea that a certain bulk or measure of food stands for a certain definite amount of energy, since each food model represents a 100-calorie portion of food, or in some cases a 50-, 150-, or 200-calorie portion. Again, the models can be used to show the foods which furnish the materials, such as calcium, iron, phosphorus, protein, and vitamins which are essential for upbuilding the body and regulating its life processes.

Finally, the models can be combined to form three daily meals, illustrating an ideal breakfast, dinner, and supper for children of the ages specified. For all these angles of teaching, supplementary data are furnished by the charts.

The preparation of models of foods like those used in this exhibit is possible only where one can draw upon the services of a corps of skilled model makers such as the American Museum employs. A temporary exhibit, teaching the essential lessons involved, could, however, easily be set up by any teacher or health worker by using the actual foods themselves. Full data in regard to quantities are given in the following paragraphs. The

block models illustrating the composition of foods could be prepared by any carpenter by cutting $1\frac{1}{2} \times 1\frac{1}{2}$ pieces into appropriate lengths and painting them with a characteristic color for each component.

In the circular which accompanies the exhibit we point out that the body must get from its food:

A. *Energy*: for the performance of the internal and external work of the body.

B. *Special Materials*: for the growth and repair of body tissues and for the chemical regulation of the various functions of the body. The most important of these are: (1) proteins; (2) mineral salts; (3) vitamins; and (4) water.

The essential facts in regard to the energy requirements of the body are presented as follows:

Food as Potential Energy

The body operates as a fuel-using machine. Such machines are supplied with energy in potential form as fuel. This fuel they oxidize, and thus release the energy in an active state for use. The human body, like the gasoline engine, is a machine of this kind. The fuel of the body is called food.

The body cannot make energy nor destroy energy. All the energy that it uses it must get from its food.

Some foods furnish only energy. Some foods, besides supplying energy, also supply materials for the growth and repair of the body.

The body uses the energy which it gets from food in two ways: (a) To perform internal work; that is, (1) to keep the heart beating; (2) to keep the chest muscles working; (3) to maintain the movements of the digestive canal; (4) to maintain the proper tone in the blood vessels; and (5) to maintain a constant body temperature, etc. (b) To perform external work in such actions as the following: sitting, standing, walking, typewriting, sewing, sweeping, carpentry, etc.

Heat energy is measured in calories. A calorie represents the amount of heat energy which will raise the temperature of a kilogram (liter) of water 1° C., or the temperature of a quart of water 1.8 degrees on the Fahrenheit scale.

The Energy for Internal Work

The energy needed for internal work is always about the same because everyone has to maintain such life processes as respiration, circulation of the blood, digestion and absorption of food, and excretion. The amount of energy needed for these essential life processes is about seventy-five calories per hour, or 1,800 calories a day. This means that the food we eat must contain at least 1,800 calories daily to keep us alive (Fig. 3).

However, 1,800 calories would not be enough for ordinary life because in order to live on that amount of energy, we should have to lie still in bed.

The Energy for External Work

The amount of energy that any one person uses varies during the day. If a man is sleeping, he uses from 60 to 70 calories of food energy per hour; if he sits up in a chair this is increased to 100 calories per hour; if he walks slowly, to 200 calories per hour; and, if he becomes energetic, his expenditure of energy goes up until in such severe forms of muscular work as sawing wood it goes up to 480; and in bicycle racing to 600 calories per hour.

Fig. 1. The traveling loan exhibit, packed and ready to send out for public school use.

ENERGY EXPENDITURE OF AVERAGE (154 LBS.) MAN UNDER DIFFERENT CONDITIONS OF ACTIVITY.

Occupation—	Calories he would use per hour
Sleeping	60-70
Awake, lying still	70-85
Sitting	100
Standing	115
Tailoring	135
Typewriting rapidly	140
Shoemaking	180
Walking slowly (2 $\frac{2}{3}$ miles per hour)	200
Carpentry	240
Walking quickly (3 $\frac{3}{4}$ miles per hour)	300
Sawing wood	480
Running	500

From tables such as these the daily needs for different occupations are computed. These range all the way from about 2,000 calories for sedentary occupations such as bookbinding and sewing, up to from 5,000 to 6,000 for such active work as is done by excavators, lumbermen, etc.

BREAKFAST

DINNER

SUPPER OR LUNCH

Fig. II. The models provided in the public school exhibits can be combined, illustrating an ideal breakfast, dinner, and supper for children of the ages specified. Supplementary data are furnished for teaching purposes.

The standard for the average man of 154 pounds weight doing fairly active muscular work is from 3,000 to 3,300 calories. The standard for the average woman of 136 pounds of the same degree of activity is about 2,500 calories.

The standard for children of different ages is given in Figure III.

A useful way to learn the energy value of foods is to picture the amounts of common foods that will fur-

nish 100 calories apiece. Such amounts are called 100-calorie portions.

Luckily, many 100-calorie portions of foods are very close to ordinary table servings:

Almonds.....12 to 15	Figs2
Apples*.....1 large	Kidney bean stew..... $\frac{1}{2}$ cup
Bread or toast*.....2 slices	Lamb stew*.....small serving
Banana.....1 large	Macaroni.....1 cup cooked
Butter or butterine*.....1 tablespoon	Milk*..... $\frac{2}{3}$ cup
Cocoa*..... $\frac{2}{3}$ cup	Oranges1 $\frac{1}{2}$
Cookies*.....2 small	Peanuts20 single cuts
Cottage cheese.....5 $\frac{1}{2}$ tablespoons	Prunes.....4
Cream.....2 tablespoons	Potato*.....1 medium
Corn.....2 ears	Sugar.....3 $\frac{1}{2}$ lumps or 2 tablespoons
Eggs1 $\frac{1}{2}$	White sauce..... $\frac{1}{4}$ cup

*Starred foods are illustrated by models of 100 Calorie portions in the school exhibit. A full glass of milk represents a 150 Calorie portion.

Certain foods which have a large fat content are very high in energy value and several 100-calorie portions would be included in an average table serving. One-hundred-calorie portions of such foods are indicated below:

Baked custard..... $\frac{1}{3}$ cup	Mince pie,slice 1 in. at outer edge
American cheese.....1-in. cube	Prunes*.....2 prunes and sauce
Ice cream.....2 $\frac{1}{2}$ tablespoons	Rice pudding..... $\frac{1}{4}$ cup
	Cream soups*..... $\frac{1}{2}$ cup

*Starred foods are illustrated by models of 200 calorie portions in the school exhibit.

On the other hand, we would find 100-calorie portions of other foods difficult to dispose of at one time; these are foods that have a large amount of water in their composition:

Asparagus.....20 stalks	Lettuce.....3 heads
Beets4	Melon1
Cabbage.....4 cups chopped	Onions4
Cauliflower..... $\frac{1}{2}$ head	Peaches3
Celery.....4 cups chopped	Spinach*.....2 $\frac{1}{2}$ cups cooked

This group of low energy foods is illustrated by a model of a 50-calorie portion of spinach in the school exhibit.

The cost of energy by the pound and the cost by the 100-calorie portion are shown in Table I for various common foods.

TABLE I.—ENERGY VALUE AND COST OF VARIOUS FOODS AS PURCHASED

	Measure equal to 1 pound	Cal- ories per pound	Cost per pound May, 1920	Cost per 100 Cal- ories, May, 1920
Grain products—				
Rolled oats.....	5-6 c.	1850	\$.07	\$.004
Cornmeal.....	3 c.	1655	.07	.004
Flour.....	4 c.	1640	.10	.006
Bread.....	1 loaf	1205	.11	.009
Meat, fish and eggs—				
Lamb, forequarter....	10-12 small pieces	1165	.20	.017
Beef, round, lean....	Piece 7x5x $\frac{1}{4}$ in.	670	.40	.06
Eggs.....	8	635	.41	.06
Fresh cod.....	Piece 2x3x5 in.	209	.20	.095
Dairy products				
Butter.....	2 c.	3605	.70	.02
Cheese.....	6-8 c., grated	2055	.42	.023
Milk.....	scant pint	325	.075	
Vegetables—				
Potatoes.....	3 medium	310	.06	.019
Carrots.....	4-6	160	.10	.062
Spinach.....	11-2 quarts	110	.10	.163
Tomatoes.....	2-3 medium	105	.40	.38
Celery.....	3-4 stalks	70	.50	.70
Fruit				
Prunes.....	28-30	1190	.30	.025
Bananas.....	3-4	300	.12	.04
Apples.....	2-3	220	.11	.05
Nuts				
Peanuts.....	2 quarts	1935	.25	.013
Sugar				
White, granulated....	scant 2 c. *	1860	.20	.01

The cost of other foods on this basis can be calculated from data given in Bulletin 28 issued by the Department of Agriculture entitled "The Chemical Composition of American Food Materials (Revised Edition)." This can be obtained for five cents by sending to the Superintend-

ent of Documents, Government Printing Office, Washington, D. C. The fuel value per pound of all common foods is given in this bulletin.

More complete tables of 100-calorie portions may be found in the appendix of the book on "Feeding the Family," by Prof. Mary S. Rose.

Bulletin 28 of the United States Department of Agriculture, mentioned above, gives the calorie values per pound of all common foods. The cost of the 100-calorie portion can be calculated from the data given if the price per pound is known, as shown in the following example:

AMERICAN CHEESE			
Calories per lb.	Cost per lb.	100 calories	Cost per 100 calories
2055	\$0.42	100	x \$0.019

The number of 100-calorie portions to the pound for certain common foods is given below.

Rolled oats	18½	Potatoes	3
Flour	16	Carrots	1½
Bread	12	Prunes	12
Beef, round	7	Spinach	1½
Eggs	6½	Bananas	3
Butter	36	Peanuts	19½
Milk	3¼	Sugar	18½

Table I shows that fresh cod and lamb at the same price per pound cost 1.7 cents and 9.5 cents, respectively, per 100 calories; sugar, even at 20 cents a pound, costs only 1 cent per 100 calories; and butter, even at 70 cents a pound, costs only 1.9 cents per 100 calories.

The last column of Table II brings out the fact that the grain products are the cheap sources of food energy, rolled oats and cornmeal being among the cheapest (.4 cents per 100 calories). Sugar and peanuts come next; while stew lamb, butter, cheese, milk, potatoes, and prunes all cost in the neighborhood of 2 cents per 100 calories. Beef, eggs, carrots, bananas, and apples are more expensive (2 to 6 cents per 100 calories). Fresh cod, spinach, tomatoes, and celery run over 10 cents per 100 calories. It must be remembered, however, that some foods, like spinach and tomatoes, which are costly on an energy basis, are very important and desirable elements in the diet for other reasons.

Special Materials Required

If the only use we had for food was to get energy from it, vegetables would be counted a luxury, for they yield only from 100 to 300 calories a pound, whereas cereals and sugars give from 1,500 to 1,800, American cheese 2,000, and butter 3,600 calories a pound.

The body has also need, however, of certain special materials of different kinds, for growth and renewal of its tissues. These special materials,—the building stones of the body,—must be provided by the same foods that furnish the energy; but since some foods are rich in these materials and other foods are relatively lacking in them, we must consider quality as well as quantity in selecting a diet. We must obtain (a) the right amount of energy from (b) the kinds of food that will supply all the special building materials we need.

The living tissues of all plants and animals are primarily made up of nitrogen-containing materials called proteins. Therefore all animals and plants must have proteins or protein building materials in their foods.

Most of our common foods contain proteins. Table II is inserted to show the percentages of protein in common foods.

The colored blocks in the school exhibit show the proportion of protein present in four common foods—apples, milk, potatoes, and beef—and the practical absence of protein in butter and sugar.

The fact must not be overlooked that some foods which

TABLE II.—THE PERCENTAGE OF PROTEIN IN COMMON FOODS

I.—Foods which contain less than 5% protein—		III.—Foods which contain from 20 to 25% protein—	
	Per cent		Per cent
Sugar	None	Veal cutlet	20.3
Butter	1.0	Cottage cheese	20.9
Cream	2.5	Shad roe	20.9
All fruits are low in protein, ranging from apples to bananas	0.4	Almonds	21.0
	1.3	Turkey	21.1
		Lean round beef	21.3
		Chicken broilers	21.5
II.—Foods which contain 5 to 20% protein—		Cocoa	21.6
	Per cent	Salmon	22.0
Chestnuts	6.2	Dried beans	22.5
Oysters	6.2	White fish	22.9
Green peas	7.0	Dried peas	24.6
Fresh lima beans	7.1		
All cereals and breads, ranging from rice to oatmeal	8.0	IV.—Foods which contain 25% or more protein—	
Bacon	16.0		Per cent
Chocolate	12.9	Ham	25.0
Eggs	13.4	Salt cod	25.4
All fish except salmon and whitefish and lobster	16.4	Peanuts	25.8
Pork chops	16.6	Cream cheese	25.9
Lamb	18.0	Tuna fish	26.6
Walnuts	18.4	Smoked herring	36.9
Fowl	19.3		

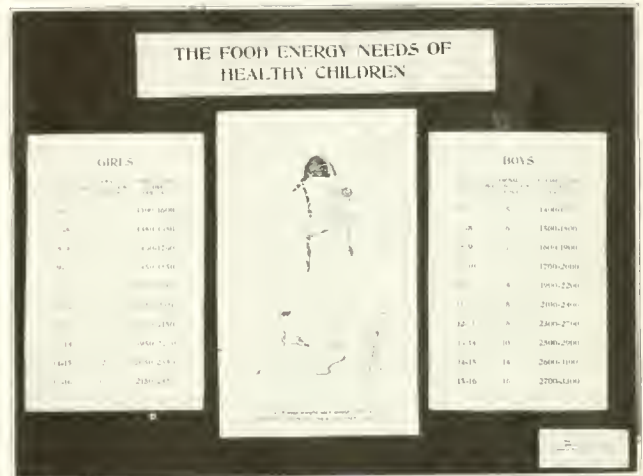

Fig. III. Some means for regular comparison with the standards for the different ages must be provided to insure taking care of the food energy needs of the growing child.

seem low in protein as expressed in percentage contribute, in fact, a large amount of our total protein. Breads and cereals are only 8 per cent protein and yet they may contribute in a normal diet one-third of the daily protein and in abnormal diets a much higher proportion. This is because we eat so much of these foods. An ordinary serving of spinach will yield 4 grams of protein, which is not bad for a food that is over three-fourths water. Because of the fact that most foods contain protein and also because the foods particularly high in protein are "tasty" foods, there is very little danger, in the case of most people, of eating too little protein. Where the income is very low or the diet otherwise specially restricted, protein deficiency may exist; but an excessively high protein diet is also harmful and is entirely too common in this country.

The function of the proteins in foods is to support growth and replace body tissues, and the proteins in some foods are not as useful for this purpose as the proteins in other foods. The most complete variety of proteins can be obtained from milk, eggs, and meat. On the other hand, eggs and meat are costly as general sources of protein. A good rule to follow is to get two-thirds of our protein from cereals and other vegetable proteins, such as beans and peas, because these are the cheapest protein foods, and to get the remaining third from the

Fig. IV. The function of proteins in foods is to support growth and replace tissue waste. The picture of the two chickens shows the result of a diet deficient in certain kinds of proteins.

complete animal foods such as milk, eggs, cheese, poultry, and meat. Milk is the best protein food for children. The result of a diet deficient in certain kinds of protein is shown in Figure IV.

The standard daily protein requirement for an adult is 75 grams a day, which is about $2\frac{1}{2}$ ounces.

AMOUNTS OF CERTAIN FOODS, EACH OF WHICH YIELDS $\frac{1}{4}$ OZ. OF PROTEIN, OR ONE-TENTH OF THE TOTAL DAILY NEED

1 egg	$\frac{1}{4}$ c. cooked beans.
$\frac{1}{2}$ pint of milk	3 slices bread
1 oz. of cheese	1 oz. shelled peanuts
1 oz. of dried fish	$1\frac{1}{2}$ cups of cooked cereal
$1\frac{1}{8}$ oz. lean meat or fresh fish.	

The standard daily protein requirement of children from 10 to 13 years is from 45 to 62.5 grams, or from $1\frac{6}{10}$ to $2\frac{2}{10}$ ounces.

Of the foods illustrated by the models in the school exhibit, lamb stew has the highest per cent of protein, but the greater part of the total daily supply is, and should be furnished by the milk, bread and cereals.

Mineral Salts Required

The body requires sixteen or more chemical elements in its food. The ordinary diet will furnish these elements in abundance except in the case of calcium, iron, and phosphorus, which are very unequally distributed in foods and are often deficient in the ordinary diet.

It is necessary to take special precautions to include in the diet foods that furnish amounts of calcium, iron, and phosphorus sufficient to meet the needs of the body, since the mineral salts determine the condition of the blood and tissues. Deep seated disturbances are likely to result if the proper balance of these elements is not furnished by the food. Fig. IV shows the effect of the lack of certain salts upon plant growth.

Calcium.—The ordinary American diet is apt to be lacking in calcium because we Americans eat too much meat, bread, fat, and sugar—foods low in calcium—and too small a portion of milk and vegetables—foods high in calcium. The standard daily calcium requirement of an adult is 0.68 grams. For children from 10 to 13 years of age the calcium requirements from 0.414 grams to 0.575 grams.

Milk is the most important source of calcium. A little over one pint a day will supply the entire needs of an adult. Children should have a quart of milk a day. Meats, highly milled grains, fats, and sugars are among the common foods lacking in calcium.

COMMON FOODS HIGH IN CALCIUM

Kinds of foods	Amounts, each of which yields $\frac{1}{10}$ of the daily requirement of an adult.
Dairy products—	
Cheese	piece 1 in. square $\times \frac{1}{2}$ in. thick
Milk*	$\frac{1}{4}$ cup
Eggs	2 eggs
Fresh vegetables—	
Cauliflower	$\frac{1}{6}$ head
Spinach*	$\frac{1}{2}$ cup, cooked
Turnips	2 medium
Carrots	scant cup, cooked
Dried vegetables—	
Beans	$\frac{1}{3}$ cup
Peas	$\frac{1}{3}$ cup
Fresh fruit—	
Oranges	$1\frac{1}{3}$ oranges
Dried fruit—	
Figs	$2\frac{1}{2}$ figs
Dates	16 dates
Prunes*	14 prunes

*High calcium foods illustrated by models in the school exhibit. Others are cocoa, rice pudding, and tomato soup, largely because of their milk content.

Iron.—The amount of iron that the body needs is very small, but nevertheless important, because iron forms a constituent of all body cells and particularly of the oxygen carrying material of the red blood cells.

The standard daily iron requirement of an adult is 0.015 grams; the iron requirement of children from 10 to 13 years ranges from 0.009 to 0.013 grams of iron.

COMMON FOODS HIGH IN IRON

Kinds of food	Amounts, each of which yields $\frac{1}{10}$ of the daily requirement of an adult.
Dried vegetables—	
Beans	$\frac{1}{4}$ cup
Peas	$\frac{1}{8}$ cup
Meat and fish	
Oysters	3 oysters
Salmon	$1\frac{1}{2}$ oz.
Beef	$1\frac{1}{2}$ oz.
Eggs	1 egg
Fresh Vegetables	
Spinach*	$\frac{1}{4}$ cup, cooked
Peas	$\frac{3}{4}$ cup
String beans	$1\frac{1}{8}$ cup, 1-inch pieces
Cabbage	2 cups chopped
Potato*	1 medium
Certain cereals and breads—	
Oatmeal*	$\frac{1}{2}$ cup
Whole wheat bread*	$2\frac{1}{2}$ slices
Dried fruits—	
Dates	8 dates
Figs	3 figs
Prunes*	5 prunes
Raisins	$\frac{1}{2}$ cup

*Starred foods, high in iron, are represented by models in the school exhibit.

Among the common foods lacking in iron may be mentioned sugars and starches, fat pork, bacon, lard, suet, butter, oils, and candy.

Phosphorus Necessary

There is less chance of a lack of phosphorus than of calcium or iron, because the foods that are high in proteins are usually high in phosphorus, too; yet it is wise to pay some attention to the phosphorus containing foods of our diet.

The standard daily adult phosphorus requirement is 1.44 grams. The standard daily phosphorus requirement of children from 10 to 13 years is 0.864 to 1.2 grams.

Until recently it was thought that the diet was adequate if it provided sufficient energy, the proper amount and kinds of proteins, and the correct balance of mineral salts, and water. It is now known that animals and human beings may be fed upon diets adequate in all these respects and yet may fail to grow or develop certain diseases which may prove fatal (Fig. V).

Besides adequate energy, proteins, mineral salts, and water, there are at least three additional dietary essentials called "vitamines." They are named as follows: (1) Fat-Soluble A vitamine, which promotes growth and protects against xerophthalmia, a diseased condition of the mucous membranes, especially of the eyelids; (2) Water-

FOODS HIGH IN PHOSPHORUS

Kinds of food	Amounts, each of which furnishes $\frac{1}{10}$ of the daily adult requirement.
American cheese—	
Cheese	$\frac{3}{4}$ oz.
Legumes—	
Dried beans and peas.....	$\frac{1}{4}$ cup
Fresh peas, shelled.....	1 cup
Nuts—	
Almonds, shelled	28 nuts
Peanuts, shelled.....	38 nuts
Grain products—	
Oatmeal*	$\frac{1}{2}$ cup
Whole wheat bread*.....	$2\frac{1}{2}$ slices
Cornmeal	$\frac{1}{2}$ cup
Meat and fish	
Salmon	$2\frac{1}{10}$ oz.
Beef	$2\frac{1}{10}$ oz.
Lamb*	3 oz.
Milk—	
Milk*	$\frac{2}{3}$ cup

*Starred foods, high in phosphorus, are represented by models in the school exhibit. Other foods in the exhibit that are high in phosphorus are: rice pudding, tomato soup, spinach, cocoa, potato and prunes.

Soluble B vitamine, which protects against the diseases polyneuritis and beriberi; and (3) Water-Soluble C vitamine, which protects against scurvy.

There is little danger of a lack of the water-soluble vitamins in the ordinary diet unless this diet is limited to very few foods. When we come to consider the fat-soluble A vitamine, the case is different. This vitamine is very unevenly distributed among our foods and it is important to choose foods that will insure an adequate supply. The fat-soluble A vitamine is found chiefly in milk, butter fat, egg yolk, leaves of plants, and glandular organs such as liver and kidneys. As a matter of fact, because of such questions as bulk, dietary habits, and cost, we depend chiefly upon milk for our supply of fat-soluble A vitamine.

Water Important in Nutrition

A surprisingly large proportion of the bodies of all plants and animals consists of water and, although water furnishes no energy, it plays an important part in nutrition. A man may live a month or more without other foods, but he cannot go without water for over four or five days, the reason for this being that all vital processes take place in solutions of which water is the basis. The blood is largely water and carries the foods in solution to the body cells. These cells lie bathed in lymph, which is also largely water and contains foods in solution. The kidneys get rid of the waste products as solutions. Hence the great need for water as a solvent.

The human body is more than three-fourths water. There is a large amount of water in most foods. In general the proportion of water in foods is as follows: Vegetables and fruits, over four-fifths water; except bananas, potatoes, corn and grapes, which are three-fourths water; milk and oysters, three-fourths water; meats, fish, and eggs, over one-half water; American cheese, bread, and prunes, about one-third water; cereals, dried fruits, and fats, one-eighth to one-tenth water; cocoa, chocolate, and nuts, very little water; and sugar, no water.

The colored blocks which accompany the school exhibit show the proportion of water in certain foods.

In order to obtain a sufficient supply of water one should

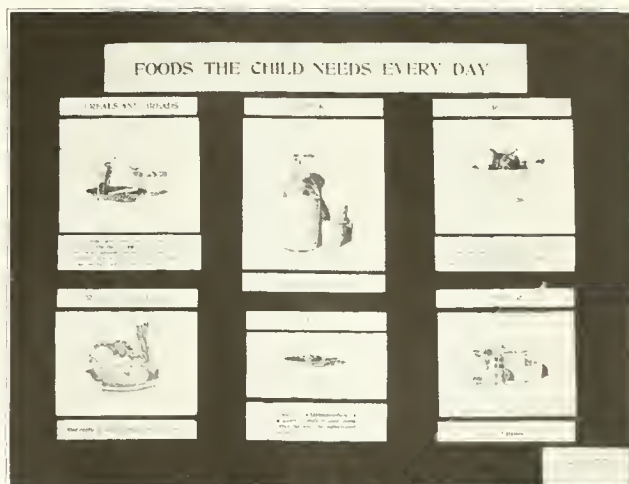

Fig. V. The most convenient manner of regulating food properly is by means of a food plan or dietary. This is a graphic presentation of the child's daily food requirements.

drink about a quart a day, in addition to the water contained in other foods.

(To be continued)

IMMIGRATION AND DISEASE

In the annual report of Public Health Service recently submitted to Congress, Surgeon General Cummings discussed the favorable conditions which exist in many central European localities for the outbreak of epidemic diseases, the saving feature of the whole situation being the restriction of travel from one country to another. In spite of preventive measures at European ports of departure, typhus fever has broken out on several of the vessels bound for the United States. The detection of the disease on the arrival of vessels at port and the measures enforced along the Texan-Mexican border have so far been effective.

While conditions in the United States probably preclude a serious epidemic of typhus fever, dire results would be produced if the infection were introduced into tenement sections of the larger cities.

SCHOOLS FOR HOSPITAL ATTENDANTS

Bird S. Coler, Commissioner of Public Welfare, was instrumental in the establishment, some time ago, of four schools in New York City for the training of hospital attendants. These schools are at the City Neurological Hospital, Blackwell's Island; the New York Children's Hospital, Randall's Island; Sea View Hospital, Staten Island, and Greenpoint Hospital, Brooklyn. The pupils are being instructed in the principles of hospital treatment and how to care for simple and ordinary sick and chronic cases. They are the first schools of the kind to be established.

SALE OF ASPIRIN RESTRICTED IN ARGENTINA

The Argentine Health Department has decided to restrict the sale of aspirin except as prescribed by a physician. For another six months druggists will be permitted to continue the unrestricted sale of those brands of aspirin or of medicines containing aspirin that are already on the local market, but no new ones may be introduced. After the six months has expired the sale of the old brands will be prohibited also, except on the requisition of an authorized medical practitioner.

CONGRESS ON MEDICAL EDUCATION

On March 7, 8, 9, and 10, 1921, a joint conference will be held in Chicago on medical education, licensure, public health, and hospitals, participated in by the Council on Medical Education and the Council on Health and Public Instruction of the American Medical Association, the Association of American Medical Colleges, the Federation of State Medical Boards of the United States, and the American Conference on Hospital Service. The program includes a symposium on graduate training in the various medical specialties, and discussion of a series of reports on clinical subjects of the medical curriculum and of matters pertaining to medical examinations and licensure. On Wednesday afternoon there will be a conference on hospital service, with tentative announcement of the following speakers: Dr. Frank Billings, Dr. S. S. Goldwater, Father Charles B. Moulinier, Miss Lulu Graves, and Miss Donelda R. Hamlin. There will be a general discussion on "The American Conference on Hospital Service," by Dr. George E. Vincent, or Mr. E. E. Embree of the Rockefeller Foundation, New York; Dr. Ray Lyman Wilbur, president of the Leland Stanford University, San Francisco; Dr. William J. Mayo, Rochester, Minn., and other prominent speakers. Thursday afternoon will be given over to the discussion of work for the public health, as follows: "From the Standpoint of the Council on Health and Public Instruction of the American Medical Association," Dr. W. S. Rankin, secretary, North Carolina State Board of Health; "From the Standpoint of the State Health Officer," Dr. S. J. Crumbine, secretary, Kansas State Board of Health, Topeka, Kans.; "From the Standpoint of the State Medical Society," Dr. F. C. Warnshuis, secretary, Michigan State Medical Society, Battle Creek, Mich.; "From the Standpoint of the State Public Health Association," Celestine J. Sullivan, secretary, League for the Promotion of Public Health, San Francisco; "From the Viewpoint of the Voluntary Public Health Association," Dr. Charles I. Hatfield, secretary, National Tuberculosis Association, New York.

GORGAS CLAIMED FOR ALL HUMANITY

Representatives from many nations assembled with prominent army and navy officers and other dignitaries attached to the United States Government assembled under date of January 16 under the auspices of the Southern Society of Washington to do honor to General Gorgas.

The Ambassador of France, Major Gen. H. K. Bethell, Military Attaché of the British Embassy, representing the British Ambassador; the Ambassador of Peru, the Ministers of Cuba and Ecuador, the Chargé d'Affaires of Panama, the Secretaries of War and Navy, Dr. L. S. Rowe, Director General of the Pan-American Union; Major Gen. Peter Charris, Adjutant General U. S. A., and General Clarence J. Owens, Past President of the Southern Society, were the speakers. Cablegrams of tribute to General Gorgas were read from the residents of Uruguay and Costa Rica and from the Government of Columbia.

Congress will be asked to make appropriation for a suitable memorial to General Gorgas to be placed in Washington, it was announced; and further tribute will be paid to the former Surgeon General by the presentation of a painting of him to the Government by the Southern Society, to be placed in the library of the Surgeon General's office.

"Gorgas honored the United States of America, but his fame and his work now belong to the world," declared

the Minister of Cuba, Dr. Carlos Manuel de Sespedes, in his speech of tribute.

After speaking of the sanitary work done by General Gorgas in Ecuador, the Minister from that country, Señor Rafael H. Elizalde, said: "He came among us with outstretched hand and purity of purpose, winning our hearts. We are proud to owe a great national debt to him."

The Ambassador of Peru, Señor Frederico A. Pezet, spoke of the way in which from 1884 to 1889 he "saw men arrive from France, full of energy, impregnated with the national trait of a courage that knows no fear, with a pride of nation and race, arrive one day to become stricken the next and but a few days later to be laid in their resting places. The scourge of the tropics more than any other cause served to defeat the French in their attempts to construct the canal. The failure of France was the incentive that made possible the victory of America." While the work of General Gorgas in Cuba had been noteworthy, said the Ambassador, it was in Panama that he reached the pinnacle of greatness.

The Chargé d'Affaires of Panama, Señor J. E. Lefevre, in his remarks said: "Although we are earnestly endeavoring further to honor the memory of our illustrious friend by the establishment of the Gorgas Tropical Institute for Research at Panama, we are doing it as a national tribute."

Major Bethell of the British Embassy said of the services of General Gorgas: "They were not limited to a nation; they were given to mankind. To us who are British they were of peculiar value, for we have many tropical possessions which present difficulties of health maintenance not dissimilar to those he faced and conquered in Panama."

Dr. Rowe of the Pan-American Union declared that "General Gorgas was, in the highest sense, a typical American. I use the word American in its broadest continental connotation, for, if the test of citizenship is service to the community, General Gorgas deserves to be regarded as a citizen of the American continent."

DR. HOUGHTON RECEIVES APPOINTMENT

It is announced from the Rockefeller Foundation that Dr. Henry S. Houghton has been appointed director of the Peking Union Medical College. Dr. Houghton, a graduate of the Ohio State University and the Johns Hopkins Medical School, has spent the greater part of the last fifteen years in China, where he has served as physician of the WuLu General Hospital, as dean and professor of tropical medicine of the Harvard Medical School of China in Shanghai, and recently as a member of the staff of the China Medical Board and Peking Union Medical College in Peking.

SOUTHERN MEDICAL ASSOCIATION

The Southern Medical Association at its closing session on November 18, in Louisville, elected Dr. J. L. Crook, of Jackson, Tenn., as president; Dr. E. H. Block, of Atlanta, first vice-president; Dr. G. A. Hendon, of Louisville, second vice-president; Dr. Seale Harris, of Birmingham, re-elected secretary. Hot Springs, Ark., was selected for the next annual meeting.

DR. ROBINSON GOES TO NASHVILLE

Dr. G. Canby Robinson resigned, July 1, 1920, his position as dean of the Medical School. He was elected to the position of professor of medicine and dean in the Vanderbilt University School of Medicine, Nashville, Tenn. He enters on his active duties there in September, 1921.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

ARE YOU TO BE COUNTED A FRIEND?

THE National Organization for Public Health Nursing is organizing state committees known as "The Friends of Public Health Nursing," as part of the plan to secure fifty thousand new members. They have stated that the United States needs five times its present number of public health nurses. This Organization is undertaking the largest piece of work in its history. It is beginning this month a campaign for increasing its membership, interesting the young women of the country in the profession of public health nursing, and inspiring the public in general to a larger measure of devotion to matters of public health. Through the press and through committee activities the entire field of school, industrial, district, and the other types of public health nursing will be presented to America's millions of people until there is a universal insistence upon the establishment of this form of nursing in every community of the United States and the lifting of nursing in general to a level not reached by it in the past.

Chairmen and committees have already been appointed in many of the states of the Union; and a program outlining the steps to be taken for the accomplishment of the end is being directed from the office of the N. O. P. H. N. at 156 Fifth Avenue, New York City. Specifically, the purposes of the work are to widen the usefulness of the organization throughout the country, to increase the lay membership by at least fifty thousand, and to raise \$150,000 for carrying out the plans of the future.

At the present time there are in this country about ten thousand public health nurses. On the basis of one such nurse to every two thousand of population, the organization hopes that by the time it has attained a lay and professional membership of sixty thousand it will eventually be able to bring about a fifty thousand increase in the number of public health nurses. Especially in those communities where there is not a single industrial, school, district, or other visiting nurse will the work be directed toward a stricter attention to matters of public health.

At the same time there will be activities looking toward a general elevation of the plane of nursing of this type. The N. O. P. H. N. has taken upon itself the task of setting the requirements for new schools that are to be opened and the endorsing of such schools already in existence. Recently it announced that eighteen courses in public health nursing had been approved and that the educational secretary was at that time making a study of still other schools and was acting in an advisory capacity for at least one school soon to be opened. Noteworthy work in the standardization of nursing may be accomplished by such an organization as the N. O. P. H. N.

Several of the states of the Union are engaged in the

consideration of legislation favorable to public health nursing and the N. O. P. H. N. is prepared to assist with problems of this kind. There is no doubt that legislation more extensive than the mere production for the education of the public on the merits of public health nursing would be of distinct value and, if this message may be brought before the citizens of this country, the Organization is confident that the other purposes of its movement will be accomplished.

But its only present hope for the spread of its message through the assistance of the public health nurses who are members of the Organization. With this in view it is the plan to attempt to enroll every one of the 10,000 public health nurses in the country in the National Organization for Public Health Nursing as a foundation for the greater membership of lay supporters. Nurses eligible may apply for membership by letter to National Headquarters at 156 Fifth Avenue, New York City.

Nurses eligible for active membership in the N. O. P. H. N. need not necessarily be engaged in public health nursing. Private duty and hospital nurses should join this Organization, which has become a clearing house for general information on all nursing problems and has been recognized as a standard bearer and publicity expert for nursing propaganda, and which has done so much to dispel the general inertia in regard to the nursing profession.

Professor C.-E. A. Winslow of Yale University, recently said:

I consider that the National Organization has rendered and is rendering and must continue to render, an absolutely invaluable service in guiding and coordinating the development of the new profession of public health nursing. I know of no other social development comparable in magnitude with the growth of public health nursing and this Organization is the one agency which can furnish the inspiration and the counsel and the organizing and correlating power to keep the growth along sound and progressive lines.

Miss Lillian D. Wald, director of Henry Street Settlement of New York City, says:

The National Organization for Public Health Nursing has been established but a few years and during its brief life it has demonstrated over and over again its usefulness—I think it no exaggeration to say—the necessity of its existence at this time. Before the organization was established, America was strewn with the remains of well intentioned but inefficiently administered nursing associations for the people. The existence of these organizations was ephemeral and that is not surprising.

Well meaning and public spirited people felt the need of the service of the nurses in the community, but the need was most apparent in remote country regions where contact with workers and their inspiration is cut off and a standard of work was not possible. Often splendid nurses were lost to the community because of their isolated situation and it required nothing less than a genius to establish a standard, secure support and understanding, and

meet the many and varied problems that arise in work of this kind.

Here and there inspired groups with a faculty for organizing, and a nurse equal to all the demands, did work out splendid systems, even in isolated regions; but this was exceptional as it would have been in any field of technical and practical service. The National Organization came into being at the psychological moment, at a time when the demand for the public health nurse was growing greater every day and when there was a danger of wrecking an instrument of value because of a casual and unprofessional method. Through the expert advice available there is no association for public health nursing in the country that cannot secure advice and help when advice and help are needed.

Despite the fact that more than a quarter of a century has elapsed since the first public health nurse, in our present understanding of the term, was established, the subject is new to the people at large and an organization like the N. O. P. H. N. is absolutely essential and will be necessary for some years to come, an organization that can assemble the best thought and the most valuable experience for the beginner and for the least experienced; that can guide and coordinate community service and standardize it so that there will be the least waste and the greatest economy of time and money.

The service to the community rendered by the N. O. P. H. N. makes available the technique and the experience that has been found successful in the saving of lives and the socializing of the homes. It is an agency which can both inspire and standardize and at the present time there is no appeal greater than the appeal to nurses and public spirited people throughout the land to use their resources and their influence for a better kind of Americans.

This has startled many into a realization of the physically unfit, but those who have traced civilization by infant mortality curves know best how much is to be done and what great fields are unexplored. Life, itself, to a very great degree, is dependent upon popularizing the science of healthful living. The nurses working in the homes and in the community have the opportunity of popularizing this science.

For that reason the N. O. P. H. N. is justified in asking for support from nurses and from others that there may be the fullest development of their contribution to our America.

Miss Julia Lathrop, Federal Children's Bureau, Washington, says:

Nursing is doubtless the newest of the professions and its right to exist as a servant of humanity is not yet fully realized.

Public Health Nursing is still newer. The power of the public health nurse to aid in the constructive betterment of social and civic conditions is realized by few.

In the large towns other agencies relieve the public health nurse of many duties which are most important in the country. The greater part of our population lives outside the great cities, indeed outside the small cities. The lack of attention to sanitation, the remoteness from help in emergencies have been described again and again but no one had devised any real remedy until the pioneer public health nurse offered herself and her Ford. She is trained in the best methods of bedside nursing and she is also trained in the knowledge of what the community as a whole needs in order to safeguard the health of the family and of the children at school or away from home. She has a steady head and a good heart and much understanding of the fine art of persuasion.

Of all this equipment Nature bestows the vigor, the aptitude, the generous courage. Training and hard work do the rest. As yet we have only the pioneer. We need thousands of public health nurses for rural work alone. It is because of the national need for public health nursing and the painful lack of nurses that this Organization is needed to (1) interest the right type of young women in the profession; (2) to secure proper training schools, based upon the needs of the student; (3) to secure the endowment of schools of nursing, as are other good schools; (4) and to serve as a center of stimulus and inspiration to the nurses themselves.

The National Organization for Public Health Nursing will have an international influence, for nowhere is the public health nurse more needed than in the war wrecked parts of Europe where she is unknown. To aid in dig-

nifying and encouraging the profession of nursing in central Europe is a worthy enlargement of the home duties of the N. O. P. H. N. The organization will not allow itself to think or act in a small way. Its possibility of service is nation-wide and world-wide.

The Organization is in need of more support by the nurses of the entire country. They are depending upon that support. Let us not fail our own Organization in this their first campaign for membership. You join—make your friends join—let us all join and do it now!

EDITOR.

CHICAGO NURSES' CLUB AND DIRECTORY

It will be of great interest to many nurses to know a little about the two-fold organization, the Chicago Nurses Club and Directory enterprises of the First District. Despite seeming competition of other nursing registries, this directory has thrived and expanded, no doubt due to the united support given us by our women in charge of the various hospitals in personally calling for nurses for duty in the hospitals and referring nurses for membership who come to their attention.

About six months ago another step was taken toward our visualized club of the future by moving the directory office and opening club rooms in a central location convenient to all nurses. Immediately the wisdom of this change was evidenced by the frequent use made of the club rooms by members, and the opportunity given the registrar for getting better acquainted with directory members with whom formerly she had had only a telephone acquaintance.

The plan is eventually to have a large club building, fully equipped with parlors, gymnasium, dining room, library, etc., and this should not be unattainable if we could secure the interest of all nurses of our city and state. It would provide accommodations for out-of-town members when visiting the city as well as privileges for local members.

INSTITUTES FOR INDUSTRIAL NURSES

Inquiries concerning Institutes for Public Health Nurses to be held during the summer of 1921 are already coming into the office of the National Organization for Public Health Nursing. The experiences of those who conducted Institutes last year proved that plans for summer conferences of this sort should be made early in the year.

It has been suggested that, in view of the great demand and apparent need for such institutes, it will be better if the responsibility for them is carried by nurses in each state or at least in groups of states, making it easier and cheaper for nurses to attend.

The *Public Health Nurse* will publish during the spring and early summer reports of institutes held in various places last year as a guide to those who are undertaking them for the first time.

ROTARY CLUB ESTABLISHES MILK STATIONS

The Rochester (New York) Rotary Club has equipped and is conducting four milk stations in the city of Rochester to save underfed babies. These milk stations are being conducted at a cost of approximately ten thousand dollars a year.

But a man is never content with the result of his work. He is ever eager to improve upon it; to discover new methods of performing it; to invent instruments and tools which will facilitate it.—*Mackenna*.

MOUTH HYGIENE FOR SCHOOL CHILDREN

By ALFRED C. FONES, D.D.S. DIRECTOR, DIVISION OF DENTAL HYGIENE, DEPARTMENT OF HEALTH,
BRIDGEPORT, CONN.

IT IS now universally conceded that the most conspicuous defect of the school child is the unhygienic condition of his mouth. The reports of the medical inspectors in the public schools who have made but a glancing examination of the mouths of our school children indicate that decayed teeth outrank all other physical defects combined. Careful dental examinations reveal the fact that it is difficult to find two school children out of a hundred with a sound set of teeth, and that the average is seven cavities per child. How to overcome the appalling condition, how to establish clean mouths, sound teeth, and the tooth brush habit,—this is the most important public health problem facing the medical and dental professions and the educational authorities of today.

School Dental Clinics the Answer

Ideas differ regarding the service which school dental clinics should render. The dental clinic which attempts to fill the teeth of school children usually fails in its purpose of materially helping the situation because it is never possible to cope with the enormous number of children needing dental attention, and such a clinic resolves itself into a fine charity for a few. In Bridgeport, Conn., we had to face the problem of 20,000 children in the first five grades alone, averaging seven cavities apiece, or 140,000 cavities. Even were wholesale extraction considered, it would require two years for a corps of twenty-five dentists properly to restore these mouths to a healthful condition. Such an expensive proposition could not be considered for the following reasons: (1) City officials do not, as yet, sufficiently appreciate the immense importance of sound teeth to good health to be willing to appropriate the large sum of money that it would require; (2) unless followed by a definite system of prophylaxis such work would be merely palliative and in a few years the same children would again be affected with dental caries, while an equal number of new children were still uncared for; and (3) until parents and children are educated to the importance of caring for the mouth, the making of such operative work compulsory would cause much trouble. But the most important reason seemed to be that, even if funds were available, the task would be hopeless because it would not stop the trouble at its source, but merely repair the damages after they had occurred.

It was finally decided to start on the preventive side and evolve a plan which could be incorporated as an active part of the school system. The result was the educational and preventive dental clinic,—a plan whereby the municipality accepted one-half of the responsibility, that of aiding and educating the children in the prevention of decay; while the home care of the mouth, and proper feeding was to be assumed by the child and his parent,—a fifty-fifty basis.

Before the operation of the clinic is described, it may be well to review briefly the causes of dental caries and the most widely accepted methods of prevention.

It has been frequently proved in private practice that 80 to 90 per cent of dental decay can be prevented by a system of extreme cleanliness and correct diet, especially in the elimination, or at least the restriction of the consumption of free sugars. For thirty years we have known definitely that the actual cause of dental caries

was the action of microorganisms on sugars and starches, reducing them to lactic acid, which is the solvent for the cementing substance joining the enamel rods. The lactic acid, in turn, precipitates the mucin from the saliva upon the teeth, forming a glue-like protection or plaque for the fermenting carbohydrates and microorganisms. The bacterial plaque is then regarded as the initial cause of dental caries. We know (1) that the frequent removal of plaques and accretions from all the surfaces of all the teeth by means of hand polishers is the most efficient means, aside from a correct diet, for the prevention of dental caries; (2) that the faithful, daily use of the tooth brush, floss silk, and a mouth wash (such as lime water prepared from coarse calcium oxid) is the best known means for the thorough removal of food débris and the dissolution of mucin; (3) that nearly all microorganisms in the human mouth are harmless if deprived of a pabulum, such as food débris, upon which to feed, develop, and multiply.

Diet the Basis of the Difficulty

It was of course realized that, although it was possible to begin at once with the actual prophylactic operative work, the educational work of the clinic would necessarily be a slow, painstaking process. When the diet of the American child is considered, it is not astonishing to find that dental caries is a universal malady. Originating, as it does, from carbohydrate fermentation upon the teeth, no other result could be expected among the children of a nation averaging nearly one hundred pounds of sugar per capita per year. The author personally believes that a well balanced diet in childhood with special emphasis upon foods of high calcium content and the elimination of free sugar, would result in practical immunity from dental caries, even in the absence of a rigid system of mouth cleanliness. The causes of susceptibility and immunity are still under investigation, but it is reasonable to believe that susceptibility is mainly in proportion to the con-

The problem in Bridgeport of caring for twenty thousand pupils in the first grade whose teeth showed an average of seven cavities each was met by training an auxiliary corps of school dental hygienists.

sumption of free sugar, and that in a great measure immunity is acquired by the absence of free sugar in the dietary. Among the peasant classes of Italy, Greece, the Balkan States, Germany and other countries, where the

diet consists mainly of coarse foods, vegetables, and fruits, but where free sugar is a luxury that cannot be indulged in, decayed teeth are the exception and not the rule. This is true also of the Esquimaux, the African Negroes, the American Indians, the Maoris of New Zealand, and many of the South Sea Islanders.

The medical profession is, to a great extent, responsible for the situation, for the family physician has taught mothers to believe that free sugar is an essential food for growing children. Under the existing conditions what chance has an American child to have sound teeth? If he is a modified milk baby, sugar is added to the milk in the proportion of one ounce in twenty, at only a few weeks after birth, and all too frequently cane sugar takes the place of milk sugar. The taste and craving for sweetened foods is developed at once and is steadily encouraged as he progresses to cereals with sugar, puddings, jellies, sweetened crackers, etc. To the normal sugar supply found in milk, vegetables, and fruits, and in the conversion of starchy foods, is added an ever increasing amount of free sugar at meal time, augmented between meals by soda water, ice cream, and candy.

There can be but one result; the deciduous teeth are attacked by dental caries. At the beginning of his school life the child presents a wrecked mouth, and it is only a matter of time before the permanent teeth are similarly affected.

It was impossible to secure graduate dentists for prophylactic work, but fortunately such service does not require a dentist. The need for semi-medically and dentally educated prophylactic workers to care for these children was the inspiration for the first training course for women, known as dental hygienists, in Bridgeport, Conn., in 1913. The efficiency of these women in carrying out educational and preventive measures is now an established fact. Our clinic was opened in September, 1914, in the first and second grades of the schools, and it was planned to conduct a five year demonstration of this type of clinic. The corps consisted of eight dental hygienists and two supervisors. There were four distinct parts to the system: (1) the prophylactic treatment, or the actual cleaning and polishing of the children's teeth, and chart examination of the mouths; (2) tooth brush drills and class room talks; (3) stereopticon lectures for children in the higher grades; and (4) educational work in the homes by means of special literature for parents. The prophylactic treatment consisted mainly in the thorough cleaning, by means of orange wood sticks in hand polishers, of every surface of every tooth. This meant that the dental hygienist would remove all stains and accretions from the surfaces of the teeth, and especially the mucilaginous films, known as bacterial plaques, which are the initial step of dental decay. The treatments were given in the schools, the equipment being portable and adapted to almost any location. Every child received the same treatment, regardless of the financial status of the parent; in short, this preventive system was incorporated as part of the school curriculum. Some parents objected, thinking the work was a charity, but with a better understanding of the project the objections were soon withdrawn.

One of the dental hygienists performing a prophylactic treatment. This gives a good view of the portable dental equipment.

The tooth brush drills were given by the supervisors, and a method of mouth brushing was taught for use in the home. No attempt was made to use water and a dentifrice in the class room as this would prove too mussy. Class room talks concerning foods, cleanliness, etc., were part of the drill. The total number of children examined and treated in the first and second grades the first year was 6,768. On the first examination less than 10 per cent were brushing their teeth daily. About 30 per cent claimed that they brushed their teeth occasionally, while 60 per cent were frank enough to state that they did not use a tooth brush. Of the children 10 per cent were found to have fistulae on the gums, showing the outlets of abscesses from the roots of decayed teeth, and they averaged over seven cavities per child. It was shocking to find the mouths of these children, ranging from five to seven years of age, in this deplorable condition, and it was appalling to contemplate the conditions that would result in these mouths as the children grew up. It presented very interesting material to work with.

In September, 1915, six additional hygienists were added to the corps to advance the work to cover the first three grades. This gave a sufficient number of workers until 1917, when six more were added, so that this care could be given to all the children in the first five grades, numbering about fifteen thousand.

Extended as a Health Measure

In January, 1918, the parochial schools petitioned the Board of Health and also the Board of Apportionment to have this system extended to them as a health measure. This petition was granted, and in September six more hygienists were added to the corps for this purpose, making twenty-six in all. At the present time these women have under their care the mouths of nearly twenty thousand children in the first five grades.

We have also employed three women dentists, who are filling the small cavities in the first permanent molars for the children in the first and second grades. Many of these children, on entering school, show small cavities developing in these important teeth, and in order that all the children may start on an equal basis in the future prevention of dental decay of the permanent teeth, all are eligible and are encouraged to have these small cavities filled.

A graduate woman dentist, who is engaged in filling the fissure cavities in six year molar teeth.

This clinic has been a pioneer work in a city with a large foreign population of which many parents do not speak English, and was carried on during the war period which necessarily produced very unsettled conditions in the schools of a large munitions center like Bridgeport. In fact, no period could have been more unpropitious for a serious demonstration of

this kind and we feel that the value of education and prevention was put to the hardest possible test.

In making this demonstration it was not our expectation to make a startling reduction in the percentage of dental decay, the main object being to show up the pernicious mouth conditions prevailing among school children and to prove the value of prevention and education in

mouth hygiene for great numbers of children in preference to extensive repair clinics with no effort to eliminate the source of the trouble. It would, of course, have been ideal to have had the two types of clinic and to have put the children's mouths in sound condition, but funds were not available for this purpose, and the excellent report shown is merely the result of education and prevention.

In order to prove definitely the value of education and prevention it was necessary to have data of the condition of the mouths of children in a higher grade who had always been without the advantage of prophylactic treatments, tooth brush drills, and education in mouth hygiene. The children of the fifth grade were chosen as a control class, and our report presents the comparison of their mouth conditions with the present fifth graders, who have had prophylactic treatments and education in mouth hygiene for the first five years of their school life. They have had no repair work provided for them, and the educational side has been three-quarters of the work of the dental hygiene corps.

The demonstration was conducted in thirty schools, and this year twenty thousand individual children received this treatment and education. Our records show that the permanent teeth of children carried through the five year demonstration show, at the end of the period, a reduction of 33.9 per cent in dental caries. One year later, in 1920, the reduction in dental caries was 49.6 per cent. The record in some schools was quite remarkable, the average in one school being 67 per cent, and several schools averaged 57 per cent.

Aside from dental decay, the most noticeable defect in the mouths of school children is lack of proper relationship between the jaws and teeth, or malocclusion. The symmetrical development of the brain case and the bones of the face, as well as good digestion, is dependent upon a perfect masticating machine. It was astonishing to note that malocclusion was present in 98 per cent of all the children examined in the past five years. This deplorable condition could be remedied to a great degree by the feeding in early childhood of the hard, coarse foods requiring pressure for thorough mastication, and by the prevention of any pernicious habits, such as thumb sucking, the use of pacifiers, mouth breathing, etc. Undoubtedly adenoids would be prevented to a marked degree if the roof of the mouth could be broadened and lowered by such pressure exerted in chewing. This would permit of wide nasal cavities that would be conducive to nose breathing and proper functioning of the nasal passages.

When but two per cent of our school children have regular teeth, it adds to the difficulty of eliminating dental decay, since irregular teeth offer the greatest opportunity for the formation of cavities, and render the thorough cleansing of the mouth very difficult.

Related to Retardation

Our superintendent of schools states that clean mouths have had a very marked effect in reducing the condition of retardation which, in 1912, had assumed alarming proportions. One needs only to consider the financial side to recognize that any reduction in retardation is an accomplishment to be sought for through all legitimate means. During the period of our demonstration retardation was reduced 50 per cent, and the cost for re-education which formerly equalled 42 per cent of the entire budget was reduced to 17 per cent of the entire budget. This really wonderful change could not be accounted for by reorganization of curriculum, or change in teaching forces, although these factors were, of course, important. It seems fair to conclude, after a detailed study of the school sit-

The municipality of Bridgeport has accepted the responsibility of caring for dental defects by training the children in preventive methods of extreme cleanliness and correct diet.

uation, that retardations are greatly influenced by the toxic effect produced by numerous bacteria in unclean mouths and in devitalized, diseased teeth. It is further conceded that tooth ache is, directly or indirectly, the cause of 80 per cent of absence from school in the third, fourth, and fifth grades.

The forms of communicable diseases, where mouth hygiene could play an important part for prevention, are those which involve the respiratory tract, or find ingress to the body through the mucous membrane lining the mouth, throat and nares. The resistance to bacterial invasion may not be determined entirely by the contents of the blood, but by the tone and resistance of the cells of the individual tissue on which bacteria may lodge temporarily. One bacterium does not produce a disease. It is only when the environment proves favorable for their propagation and the production of large numbers, that infection occurs.

Any continuous effort that has for its object the removal of dead animal and vegetable matter, such as food debris, from all the surfaces of all the teeth, the stimulating and keeping up the tone of the membrane lining the mouth, and the reducing of the numbers of bacteria in the mouth to a minimum, must act as a powerful preventive by aiding the tonsils, the soft palate and the pharynx to maintain a normal and healthful condition.

Conversely, those mouths which are neglected and contain decayed teeth with decomposing food, red and congested gums, enlarged tonsils and a palate and pharynx covered by an irritated and partly congested mucous membrane, present an ideal field for the lodgement and incubation of the pathogens. How many of the communicable diseases, that gain ingress through the mouth will finally be eliminated from child life in our public schools by an enforced system of mouth hygiene, is still a question, but all evidence seems to show that a clean mouth with sound teeth is the one most important factor for prevention.

Up to a short time ago we had no tangible records in the department of Health that pertained to communicable diseases in the children of our public schools whereby comparisons could be made from year to year of an increase or decrease in the numbers of these diseases. It is, therefore, impossible at the present time to show what obtained in the schools four or five years ago in comparison with what obtains today.

Out of the death rates from all causes in this city we have been able to find records of three diseases which

are so common among children, namely, diphtheria, measles, and scarlet fever. These are figured on a basis of per 100,000 population, and show the following:

	Year	Deaths	Death rate per 100,000
Diphtheria	1914	44	36.6
	1918	32	18.7
Measles	1914	24	20
	1918	7	4.1
Scarlet fever	1914	17	14.1
	1918	1	0.5

From the death rate tables, the general inference must be that the percentage of communicable diseases is gradually decreasing. Mouth hygiene is a very powerful factor in the restriction of communicable and infectious diseases of childhood.

Our experience has been that greater and more definite results can be obtained for the physical betterment of a larger number of children in an educational and preventive clinic than in a relief and repair clinic, though, of course, ideal service demands correlation of both services.

THE RURAL SCHOOLHOUSE

A MOST interesting book was recently issued by Jonathan H. Wagner, State Superintendent of Public Instruction, Santa Fe, N. M., called, "Plans and Suggestions for Rural School Buildings."

John Ruskin once said, "We have two great branches of architectural virtue, and we require of any building: (1) That it *act well*, and do the things it was intended to do in the best way; and (2) that it *look well*, and please us by its presence, whatever it has to do. Undoubtedly schools being built in New Mexico will *act well* if the plans of the State Department are followed, as many valuable suggestions are given in the pamphlet concerning (1) The value of school grounds, (2) the building, (3) ventilation, and (4) lighting, equipment, and arrangement. That they will *look well* cannot be questioned by any one who looks at the plans submitted by Mr. Wagner, or by any one who has traveled in New Mexico and has seen the attractive mission type of architecture so popular there.

Public health nurses who are doing rural school work would be wise to avail themselves of copies of this pamphlet which would give them excellent ideas of proper construction of rural school buildings, information which they are much in need of, not only in their sanitary inspection of school buildings, but in their recommendations for improvements to the boards of trustees of offending school buildings. Some of the subjects covered in the pamphlet are summarized as follows:

Standards for Rural Schools

I. *The School Grounds*.—Beautiful, well kept school grounds are an indication of a progressive community; the money invested in school property brings returns in enhanced farm values and in a happier, richer life for children as well as adults. The schoolhouse should be located on the best plot of ground to be secured in the district provided that it is not too far from the center of the community and has the advantage of the best roads. The fact that the district has a site is no reason why it should not be changed if a better one is obtainable.

The grounds, which should contain at least two acres, must be well drained; must contain water supply, if possible; and should provide for school gardening if older children are expected to attend school. Hence a rocky, wind-swept bit of land which is of no use for anything else will not be a satisfactory school location. Care must also be taken in the mountainous sections lest hillsides or trees shut out the light supply. The building should be far enough away from the road to avoid the dust and noise from passing vehicles.

The grounds should be entirely enclosed by a fence, a practical one being made with several strands of barbed wire or with a strip of hog wire topped with two strands of barbed wire. If the posts are painted white the fence will look well and be more durable.

One of the most important features of any school is its playground. We have changed the old idea of providing separate playgrounds for boys and girls for several reasons. Girls and boys must study together, compete with one another for school honors, go to and from school together, and they are associated with one another in the home. Then, why should they be partitioned off on the playground where there is excellent opportunity for the development of team work, respect for one another's rights, and wholesome, natural relationships between boys and girls? This latter fact is too often sadly neglected as countless errors in later youth give evidence.

There is practically no difference in the play interest of boys and girls, age being the important factor which determines variation in play. There should be a large, general playground so planned that a baseball diamond and a basket ball court can be laid out. A place is reserved for the smaller children and is provided with a sand pile and some small wooden boxes for building playhouses, in addition to such equipment as a giant stride and a slide. The older children may provide other play equipment for the little ones.

II. *The Building*.—No school building should be hastily planned, for in most cases it must serve many years and is likely to become quite inadequate for the community's needs. Each school will have different needs in such matters as size of library, amount of blackboard, and so forth; but no school should neglect such conveniences as built-in cupboards, ample cloak room space, place for dinner boxes, and bulletin board. The coat rooms are especially convenient when provided with a separate compartment for each child.

The classrooms should provide eighteen square feet of floor space for each child. In the matter of general plans consider (1) the number of teachers, grades, and children; (2) the use by community, the needs of the children coming first; and (3) general durability. Convenience and hygienic principles should never be sacrificed for architectural symmetry and fanciful plans. In this category must be included long eaves over windows which exclude light and cast shadows. The plans should include provision for such conveniences as built-in cupboards and bookcases. The room should be no more than twelve feet high and no more than twenty-four feet wide.

Sanitary Construction Important

Recommendation is made by Mr. Wagner that all public school buildings be so constructed as to conform to the following sanitary requirements:

(1) All buildings shall be weather tight, free from crevices in the floors and walls, and from leaks in the roof.

(2) All buildings shall be as nearly fireproof as possible and, if of more than one story, shall be provided with at least one fire escape for each and every corridor or hall

above the ground floor. It is recommended also that all buildings of more than one story be protected with a sprinkling system meeting the minimum requirements of the National Board of Fire Underwriters.

(3) All doors shall open outward only, and all outside doors shall be provided, in schools having more than one room, with fire-bolts on the inside.

(4) All basements or cellars shall be so constructed as to be well ventilated and dry.

The adobe school buildings recommended for New Mexico embody the best traditions of the Mission style.

(5) All future construction shall provide adequate cloak room space, including facilities for the care of wraps, hats, and other personal effects.

III. *The Foundation*.—(1) It is necessary to have one which is firm, to avoid sagging of building or racking it in strong winds, and also to help in keeping dry and warm. (2) Where no basement is finished off, eighteen inches to two feet is of sufficient height. With a basement the foundation should be at least three feet above the ground line. Additional light may be given to basement rooms by terracing the ground.

IV. *Drainage*.—All public school buildings and grounds shall be located on well drained sites. If the natural drainage is insufficient, adequate artificial drainage shall be provided sufficient to insure freedom from dampness of buildings and grounds.

V. *Ventilation*.—(1) Provision should be made for admission of warm fresh air and extraction of foul air—both entrance and exit to be on same side of room, fresh air six or seven feet from floor, foul air near floor. (2) If a jacketed stove is used, it is best placed on the west side of the building because the winds are so often from that direction. (3) Where possible, a furnace should be installed for all with the possible exception of the one-room building. (4) Class rooms shall at all times when occupied be adequately ventilated through one of the following arrangements:

- (a) Through wide open windows in mild weather.
- (b) Through window-board ventilators under other conditions, or
- (c) Through special air ducts, inlets or outlets in connection with an adequate steam, hot water or hot air heating and ventilating system.

(d) When a jacketed stove is used for heating, the jacket shall be fitted with a direct air inlet not less than twelve inches square, opening through the wall of the building against the middle, or hottest part, of the stove, and a special foul air outlet shall be provided in the baseboard on the same side of the room as the stove is located.

Illumination of Prime Importance

VI. *Lighting*.—The window space in the class rooms should be on the left side only of the pupils and should equal from one-fifth to one-fourth of the floor space. Windows in the back of the room are unnecessary and they inconvenience the teacher, who must face them. The win-

dows should extend to at least within six inches of the ceiling to three and one-half feet from the floor; to the back of the room and to within about seven feet of the front of the room. This last distance depends upon the placing of the seats; as a rule, the window farthest front will not be ahead of the front desk, thus avoiding, as much as possible, light in the face of the children. If the width of a school room is more than twice its height, the desks farthest from the window will be inadequately lighted. No room will be properly lighted if the upper half of the window is continually covered by a shade. Shades need be used only to keep out direct rays of sun light and since the folding, adjustable shades are so easily managed, no school room need be dimly lighted if the windows face east or west. If southern exposure is unavoidable, shades which permit a different light are desirable.

The tinting of the walls makes considerable difference in the brightness of a room, light buff for the walls, and a light cream color for the ceiling. The furniture and woodwork should be of light colored wood and should never be highly polished.

The location of the windows in other than class rooms is not important, the main essential being that there are plenty of them for the admission of sunshine. The requirements for windows, then, are: (1) They should be placed (a) $3\frac{1}{2}$ feet to 4 feet from the floor; (b) as near the ceiling as possible; (c) from five to seven feet from front of room; and (d) banked as closely together as possible.

(2) Window space should equal one-fifth to one-fourth of floor space.

(3) Glass doors in rooms to light hallways are permissible.

(4) Windows may be built in wall of one room to light another. Every class room shall be provided with lighting facilities which will permit adequate illumination of all parts of the room on the darkest days. Window shades shall be provided for all windows in class rooms for the proper control of lighting and the protection of the eyes

A building of this type can easily incorporate such features as will make the schoolhouse a community center.

from a glare of light, and such shades shall permit adjustment from either the top or the bottom.

No trees, shrubbery, or other obstruction shall be permitted so near any school building as materially to impair the natural lighting of any class room.

VII. *Equipment and Arrangement*.—All equipment from blackboards to library tables should be furnished for the small as well as the larger children. Too often all the blackboards are beyond the reach of the little ones, there is no little reading table in the library which they may claim, nor are there any other provisions made especially for their comfort.

(1) Blackboard in front of the room is essential in all classrooms. It should extend all the way across the room in a rural school because of the extended use to be made of it. The board at the side, between the windows and the front wall, should be twenty-eight inches wide or may be width of other in the room and a chalk rail from but twenty-four to twenty-six inches from floor—this to be for use of young children. Space may be provided

above this board for posters, etc. The board on the opposite side of the room may correspond to this. Then the board in the front and back of the room may be regular height from floor.

(2) All school desks used in any class rooms shall be of adjustable type; or, in lieu thereof, desks of different sizes shall be provided to accommodate children of varying growth.

VIII. *Coat Rooms*.—(1) Lighted, ventilated, and large enough for winter wraps, with (2) hooks adjusted to accommodate small and large pupils.

IX. *Lavatory*.—Every public school building shall be supplied where possible with an adequate supply of safe, clean, running water for washing purposes, and provided with sufficient lavatory equipment and supplies, placed, if possible, in a separate lavatory room, which is convenient and accessible.

No towel which is, or may be, used in common by more than one person, without thorough laundering after each individual use thereof, shall be provided or permitted in any public school building. A supply of individual sanitary towels may be provided, or pupils may provide their own towels for individual use.

X. *Heating*.—Unless an adequate steam, hot water or hot air heating system is installed in the school building, at least a jacketed stove shall be provided in each class room.

No unjacketed stove shall be permitted in any class room.

Every class room shall be provided with a thermometer, and the temperature of the air, when artificial heating is necessary, shall at all times, when such room is occupied, be kept at not less than sixty-five nor more than seventy degrees Fahrenheit.

Sanitary Provisions

XI. *Drinking Water*.—There shall be provided in every school building at all times when such building is occupied, a supply of safe, potable drinking water, ample in quantity for the normal needs of every school child. Every public school building shall be provided with not less than one sanitary drinking fountain of a type that will not at any time permit the mouth of the individual using the fountain to come in contact with the spout or faucet from which the water flows; or, in lieu thereof, a closed sanitary jar, tank or cooler, with a faucet shall be provided. No bucket or other open container for drinking water shall be used.

XII. *Sewage Disposal*.—All public school buildings, where a sufficient supply of water piped under pressure is available, shall be provided with a water-carriage plumbing.

Where there is water-carriage plumbing, separate toilets for girls and boys shall be provided, located, if practicable, in the school building. Such toilets shall be connected, for disposal of the sewage, with a sewer system approved by the State Commissioner of Health, or with a sewage disposal system built in accordance with general plans approved by said Commissioner.

Where there is no water-carriage plumbing, separate privies for girls and boys shall be provided. Such privies shall be well ventilated, rain proof and fireproof, and shall be constructed in accordance with general plans approved by the State Commissioner of Health.

XIII. *Cleanliness*.—School buildings, privies, and grounds shall at all times be kept in a clean and sanitary condition. Class rooms and halls, cloak rooms, toilet rooms, and lavatories shall be cleaned at least once each day.

Floor and furniture shall be cleaned, as far as possible, with dampened or oiled cloths or sweepers, or by vacuum cleaners.

No class room shall be swept while such class room is occupied.

No person shall spit upon the floor or walls of any public school building, nor shall any person throw any waste matter upon the floors or grounds of such building.

Though conforming to a general standard of service as well as artistic value, the model buildings may easily be adapted to different locations.

Suitable, adequate sanitary receptacles for waste matter shall be provided in convenient places.

Whenever any public school building shall be put to any use other than for school purposes, such building so used shall immediately thereafter and before being used for school purposes again, be thoroughly cleaned.

XIV. *Miscellaneous* requirements are summarized under the following heads:

- (1) Doors from rooms should open into corridors.
- (2) Light into a class room comes from these directions, in order of desirability: Southwest, West, South, East, Southeast.
- (3) In cold climate walls may be made double with air space between; and with waterproofed paper between for the outer walls.
- (4) Basement rooms which are used for classes or meetings of any sort should not be more than three feet below the ground level.
- (5) Eighteen square feet of floor space per pupil minimum for class room.
- (6) There should be no thresholds in the building.
- (7) An auditorium should be provided where possible. If furnace is placed at one end then there should be room for this purpose in the basement for a large room in the school of three- and four-teacher type.
- (8) Separate playgrounds for boys and girls undesirable, except that some schools may provide athletic field; even this is not to be forbidden to the girls.

DETROIT USES SHICK TEST

It has been announced by the department of health of Detroit that in the last few months the Shick test has been given to more than two thousand school children and protective treatment with toxin-antitoxin to about eight hundred. Materials for diphtheria prophylaxis will be supplied to physicians by the Board of Health, and the Department will give any desired assistance in regard to technic. It is expected that with the extension of this protective treatment a material reduction in the incidence of diphtheria in Detroit may be looked for within the next two years.

If liberty were used exclusively to do wrong, it would be intolerable, and good sense would sweep it from the earth. The supposition on which liberty is based, the condition on which it exists, is that men will use it for right more than wrong; that in the long run they will do right more often and do more that is good, than under a system of restraint.—Abbott Lawrence Lowell.

THERE IS "AN EQUAL CHANCE FOR ALL" AT NEENAH, WISCONSIN

NEENAH, Wis., is a town of only a little more than five thousand population, but they believe up there that it is "better to prepare and prevent, than to repair and repent," so they are doing all in their power to take care of those little frail children, who, ordinarily, in our small towns and cities sit in stuffy, crowded school rooms, and each spring leave school a little paler, a little thinner, until at about eighteen years of age, if not before, their names became a matter of record in a large book kept in the County Court house. The Public Health Nurse frequently spends hours going through these big books and tries in every possible way to tell the people that it is criminal to allow hundreds of young men and women to die just because law compels them to go to schools unfit for them while they are physically below par.

Many school nurses are justly proud of the open air schools and the fresh air camps that are springing into being as a result of their appeals and earnest efforts to lessen the death toll in their communities.

Miss Sallie Connor of Neenah writes concerning Neenah's new Open Air School:

We are, indeed, very happy to have been able to get this school started last March even though the Board of Education said it looked doubtful because it had not been provided for in the budget. When the matter seemed so urgent that it was stated that with their permission we would go out and get the money and also the room some place, they straightway made some provision whereby it could be taken care of solely within the Board and we secured a large, sunny, airy room on the third floor of the city hall which accommodates twenty lovely couches and twenty special desks, with room to spare for play without moving either desks or cots. The slightly elevated stage serves as a dining room, and the small dressing room at the side for a kitchenette. Our junior high school girls are given a half credit in the Domestic Science Department for taking care of the diet of these children. The students are

intensely interested in the progress the Fresh Air School children make in weight and strength.

Neenah also has a Fresh Air Camp. The project of the erection of a permanent fresh air camp was presented to the Neenah Civic Association by one of its public spirited men, permanently to provide for these children who had formerly been cared for in any available vacant farm

house. All members of the Association voted to help with building and equipping the camp. The building was made in sections in less than three weeks at the plant of the Hardwood Products Company by volunteer labor. The plant also gave their men who cared to do it, several half days time to work on building.

All materials for building were donated by merchants, manufacturers, and individuals. Trucks were donated to haul sections of building to the camp site, where the building was completely erected by all volunteers in six hours.

The running expenses of the camp are financed by an appropriation made each year by the City Council. The cost is less than five dollars per week per child exclusive of the salary of the nurse. The camp accommodates fourteen children. The children live at camp during vacation and are most happy and contented. They are under the constant supervision of the school nurse. The children rest every afternoon from one to three o'clock. Temperatures are taken every other day, all children are weighed once a week. They make remarkable gains in weight and muscle tone, and they have light, suitable gymnastics each day. It is to such fundamental training and education as this that we may look for the prevention of the breaking under strain and stress which marks our population today. The health and vigor of the race are in our keeping, and education must be planned with due consideration for physical as well as mental training.

Speed marked the willing task of erecting this fresh air camp.

At six o'clock in the morning volunteer workers were on the job.

Sections fitted together beforehand go up in rapid succession.

The camp stood complete by noon of the same day.

Men who worked after hours and on Sunday to build this fresh air camp for sick children.

The children live at the camp on the shore of beautiful Lake Winnebago, two and one-half miles from Neenah.

THE PERILS OF HEALTH

If what Gilbert K. Chesterton said in his lecture at Jordan Hall, Boston, on January 15, as reported by the *Boston Transcript*, is to be taken without reservation, it might appear that he is opposed to all governmental activity for the protection of public health. Fortunately, Mr. Chesterton gave the assurance that he does not criticize really scientific hygienic investigation. The attention of the world is too largely centered on health, he said. To think overmuch of health is unhealthy. To think rationally of disease is healthy. The glory and satisfaction of health are that the more we possess it, the more we can forget that we possess it.

He cast a volley of ridicule upon the doctor as a health adviser. For doctors he has profound respect, but they are to be called upon extraordinary occasions to deal with abnormal situations, and are not to be constituted as advisers of the community. The modern idea, said Mr. Chesterton, seems to be that, instead of being called to set a broken leg, for instance, the doctor is presumed to take charge of unbroken legs, to say when they are to be used to walk, and when to dance.

God knows why a Ministry of Health, said he, is messing its way into English politics.

Expressing his appreciation of scientific hygienic investigation, the lecturer said that the worship of health was being carried to fantastic extremes. His remarks were to be understood as applying to those who would arbitrarily impose on the people rules of conduct based upon theories of a kind concerning which he had been informed the medical profession changed its mind on an average once in six years.

MEDICINE AND INDUSTRY

The annual report of the Medical Research Council which has just appeared points out that the problems of industrial medicine are not easily separable from those of public health in general; the overwhelming majority of the people are engaged in industry, and the greater part of prevalent disease is connected either in its origin or extent with industrial occupations and the conditions of life which have been imposed during industrial development. As the matters set out in this report are of equal importance to people everywhere who are interested in the promotion of industrial health, we quote at length from the *Lancet* of January 8, 1921, whose editorial comment stated:

When, in the middle of the year's work under review, the Medical Research Committee was reconstituted as the Medical Research Council, it entered thereby into relationship with the needs of other state departments without loss of direct touch with the Ministry of Health; it came to form a constitutional nexus of a novel kind between the scientific forces of the country and the State. It would be hardly fair yet to look for results from the drawing together of this fine mesh; research is necessarily limited by the supply of well trained men of ability available to do it. But fortunately in the field of industrial medicine it has not been hard to find eager minds, and the Industrial Fatigue Research Board, as to one-half of which the Medical Research Council is responsible, has made investigations in the iron and steel trade, the cotton trade, the boot and shoe trade, the silk trade, and laundry work—the task of the Board being to combine these investigations into a concerted scheme. Great issues of health and happiness to the human race are inherent in this task, which should make an economic return altogether incommensurable with its small cost.

The outlook for Industrial medicine is full of promise. Although medical service in the factories and mines of this country, when compared with the United States, is de-

veloping somewhat slowly—due possibly to the long overdue remodelling of the office of certifying factory surgeon—nevertheless important steps are being taken. The labor world, without waiting for legislation, is busy profoundly modifying hours of work; the forty-eight hour week has come to stay; work in factories before breakfast has almost entirely ceased, with a suddenness no one could have foretold a few months ago—soon it will become merely a subject of antiquarian interest. An Act has been placed on the statute book permitting machinery tended by women and young persons to run for sixteen hours daily, from 6 a. m. to 10 p. m., so long as no protected person is employed for more than eight hours a day; the effect of this Act upon the elasticity of employment and of production may be far reaching. Full advantage is being taken of powers conferred by Section 7, Police, Factories, etc. (Miscellaneous) Act, to make orders concerned with the provision of welfare accommodation in many industries; these orders relate to drinking water, first aid stations, seats, cloak rooms, meal rooms, and rest rooms; in practice they simultaneously call into existence welfare supervision, and cannot fail to exert widespread influence upon the health of industrial workers.

The inspectorial staff of the Factory Department are being reorganized to deal with their new responsibilities, and the medical strength is being increased, notably by the appointment of a woman doctor. These officers have even further duties to anticipate, since a new Act consolidating legislation passed since 1901, when the last main Act was passed, may shortly be expected. Further legislation restricting the use of lead in paints may ere long be introduced in order to deal a last blow at plumbism, which would thenceforth become a medical curiosity.

Meanwhile, the Industrial Fatigue Research Board is settling down to its work, and, as the results of careful investigation, is publishing reports setting forth knowledge of practical value to industry and gradually revealing the laws which guide the working of the human machine. Employers reading these reports must be struck with the way in which the same ends serve the interests of productivity and of health. A new science, the science of activity and health, is here rapidly developing.

The Mines Regulations Acts have received fresh inspiration from transference to the Ministry of Mines under a special department devoted to safety and health; while an expert committee of the Medical Research Council is giving close attention to that distressing and increasingly prevalent disease, miners' nystagmus. The first great scheme under the Workmen's Compensation (Silicosis) Act, 1918, has been established; it only applies to a small but important industry, the refractories industry, which includes ganister mining; but it may well be the forerunner of more extended schemes dealing with the grinding of metals on sandstone wheels, the potteries, stonemasonry, and other industries with exposure to inhalation of silica dust. Kindred work going on in South Africa on the gold fields cannot fail, as it throws light on the etiology and prevention of silicosis, to influence in this country schemes drawn up under this Act. All in all, medicine and industry are running well in harness.

JUVENILE EMPLOYMENT IN ENGLAND

A new education act in England will completely change the whole position of juvenile employment in that country. This act provides that children under the age of twelve years shall not be employed; that children under fourteen shall not be employed in street trading; and that children over fourteen shall not be employed on Sundays, on school days before the close of school hours, or on any day before 6 a. m., and after 8 p. m. Regulations are issued governing the duties of school medical officers which should enable them fully to protect the interests of the child who is employed. Sir George Newsholme, chief medical officer to the Board of Education, in his report just issued, recommends cooperation between industrial bodies, local educational authorities, sanitary authorities, the certifying factory surgeon, and employers. It would be possible to discover what work the child is capable of doing and under what conditions he may be expected to labor without exhaustion or other physical detriment.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

FIGHTING TUBERCULOSIS IN FRANCE

AN EXAMPLE of the extension of a health campaign among a limited group of people, such as ex-soldiers, to include the entire civilian population of a country can be found in the present anti-tuberculosis program in France. Early in the war representatives of the Rockefeller Foundation sent to France brought back alarming reports as to the wholesale manifestation of clinical tuberculosis in the French army and, while the estimates given out at the time were later found to be exaggerated, yet the absence of any organized blockade against the inroads of the disease was clearly brought home to the country.

The tuberculosis mortality in France is estimated at between 12,000 and 15,000 deaths annually. Almost 110,000 soldiers were invalided from the army through tuberculosis, and these men were cared for at *stations sanitaires* and *hôpitaux sanitaires*. On leaving the *stations sanitaires* to return to their homes, these men were cared for by the departmental or district committees for the relief of tuberculous discharged soldiers.

The machinery and activities developed by these committees to care for the discharged soldier formed the basis for the present anti-tuberculosis program in France. These committees operated under private auspices though they were organized according to a plan laid down by the government and received government subsidies.

The anti-tuberculosis program in France as outlined by Bernard,¹ includes sanatoriums for curable cases, tuberculosis hospitals for the advanced cases, dispensaries for the examination and classification of patients, visiting nurses for follow-up work in the home, and boarding out of children exposed to open tuberculosis, and a general educational campaign. About two hundred dispensaries have been established in the various departments, schools for the recruiting and training of visiting nurses have been opened and eleven new sanatoria organized, making several thousand sanatorium beds available in the country.

The *stations sanitaires* and *hôpitaux sanitaires* will become civilian institutions, and the Pension Law of March 31, 1919, provides for the treatment of diseased soldiers in civilian institutions, the expense of the treatment to be refunded by the state.

Some observations by Bernard on the place of the sanatorium in the tuberculosis campaign are of interest. Since it is impossible, for financial and psychological reasons, to hospitalize all tuberculous patients, "the sana-

torium is only a partial and uncertain solution of the problem of tuberculosis . . . often, indeed, it becomes merely a school of idleness, without even the advantages as regards the general public of permanent segregation. It would be quite different if it became a school of vocational education for the tuberculous who, while undergoing treatment, might be taught trades suitable to their conditions, and directly or indirectly supplied with the means of obtaining employment."

The present tuberculosis machinery in France is only one link in the chain for controlling the disease. The social prophylaxis of the disease must include "the institution of appropriate protective measures, radical changes in housing conditions, a campaign against alcoholism, and the education of children in the matters of health."

JULES SCHEVITZ.

HEREDITY AND ENVIRONMENT IN TUBERCULOSIS

"OUT of an equally infected group of individuals equally in close contact with active and open tuberculosis, and living under identical environmental conditions, some individuals in the group develop clinically active tuberculosis while others never do. What is the reason for the differentiation?"

The above problem stated by Pearl¹ is the crux of the whole matter of the etiology of tuberculosis, a problem which many, unfortunately, have considered solved, but which still requires most exhaustive experimentation and discussion in order that the tuberculosis program can be carried on along logical lines.

It is only too often the case that tuberculosis workers allow sentiment and prejudice to sway them in the determination of a program for the control of tuberculosis. Facts based on careful research and observation should govern our activities, and not well sounding and popular opinions which have been spread broadcast among health workers in the guise of true statements of facts.

The studies made by Pearl, Pearson, and others indicate very clearly that the factor of heredity in the development of tuberculosis, which has hitherto been minimized by most workers, is of real significance in the consideration of the problem. The incidence and intensity of the influenza epidemic of 1918, for example, were not satisfactorily explained by geographical, sanitary, and other en-

1. Pearl, R.: Relative Influence of the Constitutional Factor in the Etiology of Tuberculosis, *Am. Rev. of Tuberculosis*, iv, No. 9, p. 688.

vironmental considerations alone, according to careful compilations prepared by Pearl.

"It is altogether improbable that either environment or hereditary constitution alone determines the differential incidence of active tuberculosis. It is much more likely that both factors are involved." What we need is a quantitative determination of the relative importance of each in the etiology of tuberculosis.

Krause,² while emphasizing the part of environment in its broadest conception, including habits, psychic condition, and other diseases, admits the inadequacy of scientific data with respect to the proof of his contentions. His frankness regarding the absence of conclusive evidence equals that of Pearl, whose reports stress the constitutional factors in the etiology of disease. The attitude of workers such as these, men who seek the truth, whatever it may reveal, is responsible for the shedding of additional light and knowledge on this perplexing problem.

The evidence presented by Pearl indicating the part of heredity in the etiology of tuberculosis is based on direct evidence as to the inheritance of tuberculous diathesis, evidence from the natural history of the disease and that from differential racial incidence in the same environment. In a table showing the frequency of the occurrence of tuberculosis among the blood relatives of tuberculous persons and non-tuberculous persons it is found that, taking all the generations together, a tuberculous person has 7 per cent of his or her blood relatives tuberculous, whereas a non-tuberculous person, chosen at random, has only 1.2 per cent of his or her blood relatives tuberculous, the absolute numbers involved in the two samples being approximately the same.

When the duration and extent of personal contact of these individuals with persons in an active "open" tuberculous condition is analyzed, it is found that there is a close relation between the proportion of tuberculous offspring and the percentage of close contact; in other words, the person who is exposed to open tuberculosis has greater chance for developing clinically active tuberculosis than one who is not so exposed, indicating that familial contact is beyond question a factor in determining the incidence rate of clinically active tuberculosis. The figures usually show "that when one or both parents were actively tuberculous, virtually three-fourths of the non-tuberculous offspring have been in just as close contact with active, open cases as their brothers and sisters who unfortunately developed the disease."

It has been commonly observed that the pioneer stock in newly settled communities, as in Western Canada, made up of people with vigorous constitutions, have low tuberculosis death rates, and that as conditions become more settled, making living in the new community less hazardous, there is an influx of weaker stocks, followed by an increase in the tuberculosis death rate. The great differences in tuberculosis mortality of different racial stocks have been carefully analyzed by Dublin and Baker³ and in these cases the people were living in the same general environment. This evidence also indicates the part of the constitutional factor in the etiology of tuberculosis.

The following significant remark by Pearl will have to be admitted by all scientists engaged in tuberculosis research: "The plain fact is that we are densely ignorant of the relative influence of the several factors which may

be concerned in the etiology of tuberculosis." Every assistance should be given those engaged in the working out of this important problem.

JULES SCHEVITZ.

NEW HEALTH BULLETIN

"COMMUNITY HEALTH" is the name of an attractive bulletin published by the Charleston County, South Carolina Health Department. The *Bulletin* contains several interesting illustrated articles dealing with the nature and spread of communicable diseases, also reports of the educational and sanitary work carried on by the health department. A special section of the little journal is devoted to rural sanitary problems, including clean drinking water, housing, and disposal of human excreta. Dr. Leon Banov is the full time health officer of the County.

DR. KEEN HONORED

On the occasion of his eighty-fifth birthday celebration

International.

a testimonial dinner was given January 20, 1921, in the Bellevue Stratford Hotel, Philadelphia, which was attended by many representative physicians and surgeons. A life size bronze bust of Dr. Keen by Samuel Murray was presented to him on behalf of the medical, civic, and other organizations of many cities. Dr. Keen has served in three wars as medical officer. For his services during the World War he was honored with the Belgian Order of the Crown conferred upon him by King Albert. Though in his

eighty-fourth year, he went to Europe last fall to preside over the International Congress of Physicians and Surgeons in Paris.

NURSING SCHEME IN MANCHESTER

At a meeting held in the Manchester Town Hall November 29, 1920, 130 members of approved societies initiated a nursing scheme with a view to supplying nurses for the public health office and of meeting any calls from the Insurance Committee and from the approved societies for the nursing of insured persons. The scheme involved a small contribution by each insured person, the aggregate of which would enable the staff of nurses to be adequately increased and properly paid. The extension entitles a doctor attending an insured person to call for a fully qualified nurse to look after the case.

TO THE SCHOOL NURSE

Questions to ask yourself about each child under your care: (1) Does he breathe well? (2) Are his teeth in good condition? (3) Is he too pale? (4) Has he a persistent cough? (5) Has he a running nose or running at the ears? (6) Has he any skin trouble? (7) Has he any swelling about the neck? (8) Are his sight and hearing normal? (9) What is being done to interest him in forming good health habits?

This guide is taken from "Health Education in Rural Schools," by J. Mace Andress.

PHYSICAL AND MENTAL EXAMINATION OF AMERICAN SOLDIERS

By ARTHUR MACDONALD, ANTHROPOLOGIST, WASHINGTON, D. C.

THE initial selective draft of 1917 furnished a good opportunity to estimate the physical condition of the male population of our country. Out of about ten million males registered, from twenty-one to thirty years of age, there were measured and examined physically, at local boards, about two and one-half million men, of whom about seven hundred thousand, or 29 per cent, were registered on physical grounds. Subsequently 3,208,446 men were examined by local boards up to September 11, 1918. Out of these two groups during the period down to May, 1918, about one million men were sent to mobilization camps, and their physical defects were recorded. It is the defects of these first million recruits which we desire to study, based upon the report of the Surgeon General of the Army.¹

The conclusions from the results of examination of the first million recruits, though tentative, probably indicate general truths. The severity of the physical examinations varied with the different camps, due largely to the various ideals of the examining boards. Facts as to disabilities, though mainly important for military considerations, are not without significance for civil life, for soldiers come from every class and section and are quite representative of the virile male population.

It will be seen from Table I that of the first million men examined 65 per cent were accepted as qualified without defects, 29 per cent as qualified with defect, and 5 per cent rejected.

TABLE I.—MILLION MEN EXAMINED JUNE, 1917, TO MAY, 1918

	Num- ber	Per cent
Men accepted as qualified without defects.....	613,797	65
Men accepted as qualified with defects.....	294,875	29
Men accepted with defects for operation.....	185	1
Men accepted for limited service.....	2,134	
Men rejected.....	52,915	5
Total men examined from each state.....	994,206	100

Rejections at the Mobilization Camps

The rejections at camps as a result of physical examinations were as follows:

	Per cent
Imperfections in the sense organs.....	21
Mechanical defects.....	20
Circulatory defects and diseases.....	15
Tuberculosis and venereal diseases.....	15
Skin and teeth.....	10
Nervous and mental troubles.....	9
Developmental defects.....	6
Other defects.....	4
	100

The Handicap for Civil Life

Since in war men must often move on their feet great distances in short times and carry a load of forty pounds or more, it does not follow that, though physically unfit for such service, they are not fit for the duties of civil life. Thus flat foot or hernia may keep a man out of

military service, but may allow him to do his work in civil life well and in good health. The tension and stress in the trenches require strong senses and heart action in a much higher degree than in civil life. Yet nervous and mental disabilities, tuberculosis, and venereal diseases are a handicap in all kinds of life. Taking everything into consideration, it is estimated that about one-half the men rejected for general military service are not seriously hindered from activity in civil life.

The Men at Mobilization Camps

Table II, Part 1, presents the comparative frequency of various diseases and defects found in mobilization camps in first million draft recruits, giving ratios per one thousand recruits for the entire United States. The defects are arranged in order of their frequency. Flat foot is by far the most common defect, affecting nearly 18 per cent of the total number examined. Venereal and throat diseases are next in frequency to flat foot; but hernia, when inguinal rings are included, will stand second in order in place of venereal disease, which will then be third.

TABLE II.—FIRST MILLION OF UNITED STATES SOLDIERS

Cause of Rejection	Part I.		Part II.	
	Num- ber	Per 1000	Men Rejected Num- ber	Per cent
Flat foot.....	176,424	177.45	2,496	1
Venereal diseases (all).....	28,826	29.99	1,217	4
Throat diseases.....	24,132	24.28	47	..
Gonorrhea.....	23,311	23.41	490	2

Goiter, exophthalmic.....	463	0.46	444	95
Cardiac Arrhythmia, etc.....	446	0.45	409	90
Psychopathic (Constitutional).....	396	0.40	308	77
Drug Addicts.....	309	0.31	297	96
Myocarditis.....	286	0.29	270	94
Alcoholism (chronic).....	181	0.18	168	92
	94	0.07	70	74

Only 2 per cent of cases of gonorrhea were rejected, while 35 per cent of the syphilitic were discharged. Diseases of the throat show very few discharges,—only 47 out of 24,132 cases.

Heart diseases consisted of 7,157 cases of valvular and

1. Ireland, Love, and Davenport: Physical Examination of the Million Draft Recruits—Methods and Results. War Department, Office of the Surgeon General, Bulletin No. 11, March, 1919. Washington Government Printing Office.

endocardial involvement, 181 cases of myocarditis (see end of table II), and 526 cases of cardiac hypertrophy and cardiac dilation; there are also listed 396 cases of cardiac arrhythmia and tachycardia, making in all 8,260 cases. As will be noted from the table, the valvular diseases constitute the great majority of the cases, of which 5,429, or 76 per cent, were rejected. The detection of valvular disease and endocarditis is considered most difficult in physical examination. While cardiac murmurs are the most certain physical signs of valvular disease, yet they may occur in healthy hearts under excitement and exertion, such accidental murmurs being systolic in time. Also, irregular heart action may be caused by the excessive use of tobacco. Soft systolic murmurs, frequently heard in growing youths, are also functional and temporary in their nature. Usually no murmur was considered organic unless there were secondary physical signs, as cardiac enlargement, edema, or cyanosis. Cardiac arrhythmia and tachycardia, that is, irregular and rapid heart action, are functional (see near end of table); 396 cases were found, of which 308 were rejected.

Eye defects.—Diseases of the eye were very common defects, and especially defective vision; refractive errors of the eye, including myopia (short sight), hyperopia (far sight), and astigmatism, included with all other defects, make a total of 9,220 cases.

Varicose veins.—Many defects were dependent upon weakness in the walls of the veins, causing varicose veins, varicocele, and hemorrhoids. Adding all these cases, as listed in Table II, there are 5,771 cases, or 5.8 per thousand of men examined. Only 801, or 14 per cent, of these were rejected, showing such defects to be for the great part remediable.

Otitis media is a very common cause for rejection, 74 per cent of such cases being rejected.

Mental deficiency.—In the physical examination there were found 2,431 cases; 85 per cent were rejected. It is thought additional cases later were detected and rejected as a result of the psychological examination. Major Yerkes, who was at the head of this work, estimates that from 1 to 1½ per cent of recruits who arrived at mobilization camps were subsequently rejected for mental defects which were revealed by special mental tests.

Defects of the feet.—Hammer-toe, hollow foot (pes cavus) pronated foot, deformities of foot, and ingrowing nail constitute the other defects of feet, aside from flat foot. These defects are generally caused by misuse or mishandling of the feet. As given in table, there were 6,994 cases, affecting 0.7 of 1 per cent of the men examined. Of these 604, or 8 per cent, were rejected. Attention might be called to the fact that overriding toes, if excessive and numerous, are liable to cause blisters in marching and are cause of rejection. If mild in degree, they may improve after wearing of the army shoe.

Underweight is an important cause of rejection, 64 per cent of such cases being rejected.

Ankylosis.—Stiff joint, bony and fibrous, caused rejection of 36 per cent (2,584) of the cases found.

Malunion of Fractures.—Fifty-one per cent of these cases were rejected, the decision depending upon the degree of malunion.

Congenital defect of the testes occurred in 1,802 cases; 302, or 16 per cent, were rejected.

Mental and Minor Nervous Diseases

The defects now to be noted belong to mental and minor nervous diseases.

Exophthalmic goiter.—Hyperactive secretion from the thyroid gland was found in 446 recruits, of whom 409,

or 90 per cent, were rejected. Simple goiter, or enlargement of the thyroid gland, was much more common, there being 1,834 cases, showing 266, or 15 per cent, rejections.

The physical examination standard required the rejection of all forms of insanity. Cases of emotional instability, as psychoneuroses, hysteria, neurasthenia, etc., numbered 453, 95 per cent of whom were rejected.

Tuberculosis.—The rules required the rejection of cases of pulmonary tuberculosis; the difficulty, however, of recognizing dormant cases is well known. There were 4,911 cases of pulmonary tuberculosis discovered, of whom 4,519, or 92 per cent, were rejected.

Some further defects in Table II may be noted, as defective hearing, in which 63 per cent were rejected; skin diseases, in which only 4 per cent were rejected; and scoliosis, or curvature of the spine, of which 51 per cent were rejected. The incidence of dental caries and defective teeth reached the ratio of nearly 5 per thousand men, 67 per cent of whom were rejected.

Compares Urban and Rural Districts

In the comparison of the incidence of disease and defects in urban and rural districts, about forty-five thousand inhabitants or more constitute an urban district. Districts with less than this were classed as rural.

In Table III are presented, for urban and rural districts, an approximation of the number and per cent of the first

TABLE III.—COMPARISON BETWEEN URBAN AND RURAL DISTRICTS AS TO CAUSES OF REJECTION

	Urban		Rural	
	Num- ber	Per cent	Num- ber	Per cent
Recruits (first million).....	377,020	100.	506,965	100.

Defects found in camps.....	144,233	38.25	168,609	33.35

million recruits, accepted without defect, accepted with defect, and rejected. It appears that the relative number rejected was the same for both urban and rural districts, being 5 per cent, but that in the rural districts 5 per cent more were accepted without defect. In the last line of Table III is given total number of defects and the percentage of all defects.

Table III mainly concerns a comparison between urban and rural districts as to rejections. It will be seen that, as to pulmonary tuberculosis, relatively more with this disease come from the rural districts. This is also true of mitral insufficiency, arthritis, epilepsy, trachoma, asthma, skin diseases, and pronated foot. It is thought that the greater amount of epilepsy in rural districts is due to the greater frequency of consanguineous marriages there.

In the other causes for rejection shown in Table III, as defective vision, otitis media, hernia, drug addiction, etc., the urban districts lead. Otitis media appears to be

greatest where population is concentrated, especially in slum areas. Chronic alcoholism and drug addiction are so much greater in the cities that they might be called urban evils.

Distribution of Defects

From tables not here given the distribution of defects discovered in the mobilization camps may be generally noted. There was a large amount of flat foot in the agricultural zone extending through Illinois, Missouri, Kansas, Nebraska, and Colorado. There is a small amount of flat foot from the southern states, due in part to the negro population, which is normally flat-footed; also a large proportion of the rural male population of the South during early life goes without shoes. With the exception of Maine, hernia is high in the New England States, New York, Ohio, Illinois, and Wisconsin, this preponderance possibly due to the large cities, as urban districts are more disposed to hernia.

Venereal diseases were found very predominant in the southern states, the ratios being affected by the negro recruits. Throat diseases were found to be highly prevalent in Massachusetts, Vermont, and New Jersey. Heart disease with valvular involvement was found especially in recruits from the Great Plains region and the mountainous country of the Northwest, but was least frequent in the central and middle states. Also, cardiac hypertrophy and dilatation were frequent along the Atlantic seaboard, in the New England and middle states, and especially in Virginia and the Carolinas. Defects of vision are especially frequent in New England and New York City, where there is a large foreign population. In New York State much defective vision is traceable to the Polish Jews, who show a large proportion of bad eyes. Varicose veins are found especially in mountainous regions of the extreme Northwest, and in Minnesota and Wisconsin. Hemorrhoids are very frequent in the recruits from the southern states, due to the negro population. Mental deficiency shows greatest incidence in the southern states, due to the negro population. The foot defects are more frequent in the more northern states, which may be due to factors already mentioned; but a large proportion of the youth of the Gulf states are brought up without shoes, which tends to promote the health of the foot. Ankylosis is especially frequent in recruits from the northern tier of western states—Washington, Idaho, Montana, North Dakota, and also Minnesota and Montana.

Underweight is frequent in recruits from Georgia and Alabama, due probably to the hookworm. There is also a high amount in New England, New York, and New Jersey, probably due to the influence of the Mediterranean race and of Polish Jews in those states. Defective physical development and deficient chest measurement are frequent in the southeastern states, probably due to hookworm; in New England, also, these physical defects are prominent, due probably to immigrants of races of short stature; the low incidence of such defects in the Dakotas and other Great Plains states is probably due to the physically larger European races who have settled there.

Goiter is especially frequent in the mountainous states of the north. Tuberculosis is most frequent in recruits from the southern states, due to the negro element; the lowest amount of tuberculosis is found in states adjacent to the Great Lakes and North Dakota.

Tuberculosis (pulmonary), venereal diseases, and valvular heart disease are inversely correlated with the density of population. Defects of vision, including astigmatism, are directly correlated with the size of cities.

Mental engineering, as it has been called, is the great

object of the organized war service of American psychologists, that started in an informal meeting in the spring of 1917, when they asked themselves what they could do to help win the war. The answer to this question has resulted not only in a war measure, but is a permanent contribution to the organization and utilization of human forces. One of the immediate results of this effort is the Army mental tests.²

Up to November, 1918, the Army mental tests had been given to 1,726,966 men, of whom 41,000 were officers. More than 7,800 men had been recommended for immediate discharge, 10,014 for labor battalion or other service organizations. Nearly 30 per cent of the 1,566,011 men were found to be unable to read and understand newspapers and write letters home. Approximately 83,000 individual examinations were made.

Group and Individual Examination

After repeated revisions of methods the procedure finally adopted provided for two types of examination—group and individual—the former to save time, the latter for reliability and fairness to the individual. There were two kinds of group examinations, one for men able to read and write English fairly well, called "Alpha," and the other for persons not able to read and write English well, called "Beta."

The group type of examination for groups numbering up to five hundred consisted of eight tests, as follows:

Test 1.—To listen and carry out commands. When "Attention" is called, to stop instantly and hold pencil up.

Test 2.—Arithmetical problems. How many are five men and ten men? If you walk five miles an hour for three hours how far do you walk?

Test 3.—Practical judgment. Why do we use stoves? Because they look well; they keep us warm; they are black. Here the second answer is the best and is marked with a cross.

Test 4.—Synonym and antonym. If the two words of a pair mean the same, or nearly so, draw a line under "same." If they mean two opposite, draw a line under "opposite." If not sure, guess:

good—bad	same—opposite
little—small	same—opposite

Test 5.—Disarranged sentences: The words "A eats cow grass" should make a sentence, if arranged in right order: "A cow eats grass," and this statement is true.

Again, the words "Horses feathers have all" should be put in the right order, "All horses have feathers," but this statement is false.

A eats cow grass.....	true—false
Horses feathers have all.....	true—false

Test 6.—Number series completion.

2	4	6	8	10	12	14	16
9	8	7	6	5	4	3	2

The test is to look at each row of numbers and on the two dotted lines, write the two numbers that should come next.

Test 7.—Analogies.

sky-blue: grass-table, *green*, warm big
 fish-swims: man, paper, time, walks, girl
 day, night: white, red, *black*, clear, pure

In each line the first two words are related in some way. The test is to see what the relation is between the first two words, and underline the word that is related in the same way to the third word.

Test 8.—Information. People hear with the eyes, *ears*, nose, mouth. France is in *Europe*, Asia, Africa, Australia.

The correct word is to be underscored or the word which makes the truest sense.

These examination tests are mainly for illiterates.

2. Yoakum and Yerkes: *Army Medical Tests*. Published with the authorization of the War Department, New York, 1920.

They consist of seven tests: (1) Maze, (2) Cuve analysis, (3) X-O series, (4) Digit symbol, (5) Number checking, (6) Pictorial completion, and (7) Geometrical construction.

This Beta group in effect is (not strictly) the Alpha group translated into pictorial form, so that illiterates or those not familiar with English might have a proper examination. Some of low mentality, of foreign birth, or with peculiarities of behavior, were required to take either two or three examinations.

Grades of Intelligence

These group examination tests, though influenced some by education and environment, nevertheless measure in the main the native intelligence of the individual. Each group, Alpha and Beta, requires about fifty minutes.

While intelligence is one of the most important factors of military service, moral characteristics are also of great worth, such as reliability, bravery, ability to lead and "carry on." It will be found also in military as well as civil life that individuals with high intelligence are much more liable to stand high in moral characteristics when temptations come than those of lower degrees of intelligence. In these tests the ratings of men are a fairly reliable index of ability to learn, to think quickly and accurately, to analyze a situation, to maintain a state of mental alertness, and to comprehend and follow instructions.

The score depends little or none upon schooling; some of the best records were made by men who had only a grammar school education. They were rated as follows: A.—Very superior intelligence, representing only four or five per cent of the draft quota.

B.—Superior intelligence, attained by eight to ten soldiers out of one hundred.

C+.—High average intelligence, including from 15 to 18 per cent of all soldiers.

C.—Average intelligence, representing about 25 per cent of all soldiers.

C.—Low average intelligence, including about 20 per cent of soldiers.

D.—Inferior intelligence, being about 15 per cent.

D and E.—Very inferior intelligence, the majority are below ten years in mental age.*

General Psychological Classification

Table IV gives a summary of a general classification based upon psychological examination. Under the second column, "White Draft," is presented a random sampling of the 1,726,000 men examined.

The third column, headed "Recruits," is a small group brought out by sorting. Under "Privates" in column four

is designated a random selection of men reported as being in infantry, artillery, machine gun, etc. The other columns are results of sampling. The group under "Sergeants" includes all classes of sergeants; medical officers are included in percentages given. Further evidence indicates that the tests will be successful in field operations. Table IV indicates a general correspondence between degree of intelligence as shown by mental tests and the actual rank of soldiers in the Army.

Tests Distinguish Low Grade Men

Men for commissioned officers are found mainly in "A" and "B" classes. As more than one-fourth of enlisted men rate as high as "C," high average intelligence, it is not usually necessary to go below this grade in choosing non-commissioned officers; also, men below are rarely equal to complicated paper work. The Army mental tests help in the prompt recognition of low grade men, which is of great military importance. Men in the disciplinary group, men having difficulties in drill, men called unteachable, and those designated "poorest" by officers show large percentages ranking below the average in psychological examinations. Negroes rank much lower mentally than whites, and southern negroes rank also lower than northern negroes in mentality.

Mentality Most Important Factor

When soldiers are assigned to training lists without regard to intelligence, extreme inequalities of mental strength of companies and regiments appear, and a very serious result is the risk of weak points in the Army chain. There is also much difference in the intelligence of officers in different arms of the service, where mental tests could render aid. In brief, degree of intelligence is probably the most important single factor in determining a man's value to the military service.

Tests Applied to Other Fields

The Army mental tests may be used in the admittance of students to college and in the educational guidance of students. The probable error of the score in Army mental tests for literates is five points. The correlation of these tests with other mental tests are as follows with (1) officers' rating of their men is 0.50 to 0.70; (2) Stanford Binet, measurements 0.80 to 0.90; (3) Trabu Band C completion tests combined 0.72; (4) with examination Beta and Stanford Binet 0.94; (6) (a) with school teachers' ratings 0.67 to 0.82, (b) school marks 0.50 to 0.60, (c) school grade location of thirteen and fourteen year old pupils 0.75 to 0.91, (d) age of pupils 0.83.

Mental tests will probably in the future aid in defining racial likenesses and differences.

The relations of illiteracy to insanity, feeble-mindedness, mental deficiency, temporary mental aberrations, immoralities, and prostitution have been studied but little, though their importance is great. In the Army the relation of mental deficiency to the morale may be vital; military crime may have its main cause in mental feebleness. Breaches of discipline may often be explained through mental tests. In a study of the disciplinary barracks cases of desertion were found to correlate positively with low mentality; on the other hand, in a study of conscientious objectors, mental tests showed that they stood above the average in ability.

The mental tests in the Army showed that intelligence increases as we go from unskilled labor to occupations of higher order, especially professional positions.

A student personnel bureau has been proposed to obtain data about each one, to find the main requirement of dif-

TABLE IV.—RELATION OF INTELLIGENCE RATING TO RANK

Score	White Draft	Recruits	Privates	Corporals	Sergeants	2nd Lieut.	1st Lieut.	Captain	Majors	Above Major
1	2	3	4	5	6	7	8	9	10	11
A	7.4	9.3	16.1	24.0	59.4	51.7	53.4	64.4	63.6

*That is, below the intelligence of a normal child at ten years of age.

ferent professions and to enable the student, through knowledge of his own abilities, to find that profession or occupation to which he will probably be best adapted, and thus reach his maximum of service and success in his career in life. Some of the results achieved in the Army mental tests are: (1) The Assignment of an intelligence rating to every soldier, based upon systematic examination; (2) finding of men of superior intelligence, indicating the desirability of advancement or special as-

signment; (3) prompt selection for development battalions of men so inferior intellectually as to be unsuited for regular military training; and (4) the early discovery and elimination of men of so inferior intelligence that they cannot be used in any line of military service.

As the mental tests were for immediate assistance and practical purposes, many studies of scientific interest were omitted, though mental appraisal is of basic importance in placing and in conditioning the individual.

CERTAIN CLINICAL ASPECTS OF THE FRAMINGHAM HEALTH DEMONSTRATION

BY ARTHUR K. STONE, M.D., ADMINISTRATIVE ADVISER, COMMUNITY HEALTH AND TUBERCULOSIS DEMONSTRATION, FRAMINGHAM, MASS.

THE question is often asked: What is the concrete gain to which the Framingham Demonstration is able to point? This question was asked and answered by a committee of medical and social experts and has been printed in a report of this committee to former Surgeon General Rupert Blue of the United States Public Health Service, under the title of the "Report of the Committee on Appraisal for the Framingham Community Health and Tuberculosis Demonstration," October, 1919.

Not a Therapeutic Experiment

If the question is asked from the clinician's point of view, namely, treatment, meaning therapeutics, it can be answered very briefly, nothing. Studies in treatment and therapy must necessarily be carried out where there are a large number of patients who as a distinct group can be put under some particular method of treatment; or, when there are sufficient numbers to be divided into groups, where various forms of therapy may be undertaken for comparative study. Framingham has no group of patients segregated; therefore, no therapeutic results must be expected from this work. Those who are looking for the results of tuberculin or "serum" treatment, the value and place of artificial pneumothorax, heliotherapy, actinotherapy, calcium therapy, a discussion of the proper time for rest and exercise, occupational therapy, etc., etc., will have to look for them in the reports of progressively managed sanatoria, and not in the reports of the Framingham Experiment.

The Framingham Demonstration is essentially a medico-social study with an attempt to assist in all moves made by the citizens to better their health conditions and wherever possible to stimulate the people to new measures of tuberculosis control and the health betterment of the town.

In order to bring about these results it was necessary first of all to show how much tuberculosis was present among the inhabitants of the town. This was accomplished by a series of medical drives wherein there were examined in all about three-fourths of all the population of the town. Tuberculosis is a reportable disease, so that the number of cases when found, through whatever source, are then made known to the Board of Health.

The accomplishment of this extensive medical examination was brought about in several ways: First, a sickness census made by the insurance agents and the nurses; this showed 14 new cases; then two drives were instituted in each of which about 2,500 people were examined; later, a large number of men were examined for the draft board. After this came the "flu" epidemic,

which brought in still more, who were examined before they went back to work; and, further, more than two thousand school children were carefully examined by the school physician. Special groups were examined at the baby clinics, in the factories, and in the summer camps, and 460 little children were examined in a tuberculin study. In all, twelve or thirteen thousand persons were examined. The good results obtained from this work were, (1) a knowledge of the amount of tuberculosis in the town, and (2) an education of all the 12,000 persons examined by the calling attention of all these people to the desirability of attending to their health. Even those who were practically well had small defects called to their attention, and were told where to go and what to do in order to remedy the defects.

Examinations Were Startling

As to the amount of tuberculosis in the community, the results of the examinations were startling. Starting in 1917 with twenty-seven known cases reported by practicing physicians, at the end of the next year this number had increased to 181 cases. About 1 per cent in the group examined appeared as active cases, and another 1 per cent could from the history and the physical findings be recognized as arrested tuberculosis cases.

Here was a result showing a much greater amount of tuberculosis than had been expected. Six to eight active and arrested cases to each death was what had been the usual estimate here in Massachusetts. The number in Framingham jumped to ten active cases to each death, and another group of ten arrested cases dwelling in the community and practically heretofore unrecognized.

The accuracy of the findings of the first group has since been confirmed by cities such as Manchester, N. H., where careful work has disclosed as many as ten active cases to each death. The study of the second group, the arrested cases, to see how they act as a contributing factor to the active cases, has never previously been made. This group of arrested cases has been recognized and warned of the danger and their subsequent life history has been carefully followed.

The development of this extensive survey, with its accurate answer to the question—how much tuberculosis is there in the town?—together with the follow-up work for the care of these tuberculosis cases, has given an answer to a question often asked by legislative committees and persons interested in the economics of the care of the tuberculous: How many beds are required to house the tuberculous sick?

The reply has been made, "one bed to each death is the ideal." In Massachusetts the county hospitals were designed in the first place to provide one bed for every two deaths, but with only a part of the hospitals already designed and constructed, during the past three or four years the number of cases seeking admission has been much smaller than the number of beds already provided. What is the reason? Framingham gives a clear answer. Knowing of the large number of cases of tuberculosis, and with the sufficient machinery for follow-up work, the ideal quota of beds is filled and kept full. They are all needed in any community when the tuberculous patients are found and are properly instructed and shown the desirability of sanatorium and hospital treatment. Indeed, in spite of the fact that Framingham is able to use a bed for every death, there are still a number of persons in the town who are having in their homes inadequate treatment for the disease. These people resist all efforts to have them go to sanatoria and also call for a physician's advice only when some exacerbation makes them acutely ill.

Follow-Up Essential

If the Massachusetts towns and cities having tuberculosis clinics followed up their cases as carefully as should be done, there is no question that a waiting list at the sanatoria and hospitals would reappear. Should financial hard times come, doubtless the present supply of beds would quickly be used up just as rapidly as they emptied during the flush times of the war period; but Framingham has demonstrated that, with intensive follow-up work on the part of the physicians and nurses of the town, even in the period of high wages, a bed for each death is needed to care for patients that are ready and willing to receive treatment if only the matter is properly put to them and the way made easy to carry out the advice.

In a study of 460 children under seven years of age with tuberculin, 33.3 per cent were found to be reactors. Two and a half years later, of these 150 reactors, only one is known to have developed into any form of tuberculous disease. The others are for the most part specially hale and hearty children not even showing evidences of malnutrition.

This is a most important clinical contribution, for it demonstrates clearly that if a child shows a tuberculin reaction, it does not by any means follow that there is tuberculous disease. It must also make it evident from the above that in case of malnutrition a positive reacting case may not necessarily mean that tuberculosis is causing the disturbance. On the other hand, it does make it probable that the positive reacting case manifestly sick, in the absence of other diagnosis, is active tuberculosis. This, it will be seen, is by no means as dogmatic a statement as has been made by Dr. Levinson of Chicago in a recent article in *MODERN MEDICINE*.

There are other points in this study which throw a certain amount of doubt upon usual interpretations of negative findings in the tuberculin test which are hard to reconcile with the findings of others.*

A result of the four years' work in the community has been to establish a general sentiment for good health. This is possibly hard definitely to define, but it shows itself by a general desire to respond to health appeals, and by less fear and suspicion on the part of the employees and people in general towards any health work which may be inaugurated in the factories and the

schools. Physicians' advice and examinations have been sought in a gratifying manner, this being seen especially immediately after the "flu" epidemic.

This attitude of mind has been brought about by the educational effect of the drives, the Demonstration, the health letters, the camp for the children, and the work in the schools, extending as it does to the homes. The publicity has been continuous and the needs and value of the hospital to the citizens have been emphasized. The value of the honest physician has been pointed out. Symptoms calling for advice have been given prominence in the local papers and persons with such symptoms have been urged, after having had the physical examinations, to have the affair followed up, and a physician's advice taken.

A most important study has been inaugurated recently to try to account for a certain number of cases of advanced tuberculosis which appear in spite of all the machinery that has been devised to catch them in their early stage. This, when complete, will throw more important light on the amount of tuberculosis in a community, and what the reservoir is from which the seemingly inexhaustible cases are drawn. It must be remembered in starting on this study that one-fourth of the town, in spite of all the elaborate attempts to get physical examinations, has not been reached; further, that in every American town and city, there is a very large movement both into and out of the community, and that consequently our number examined is probably less than three-fourths of the present population. In no sense is the Framingham Demonstration to be considered a clinical or a therapeutic experiment. Nevertheless, the work that is being carried on by the Community Health Demonstration is right in the line of the advance which has been pointed out by Sir James McKenzie in his recent and most inspiring book, "The Future of Medicine." Here in Framingham, as nowhere else, are the beginnings of disease being watched and studied. Sooner or later information will be available which will at least aid in the solution of many of the much debated tuberculosis problems.

NATIONAL CHILD HEALTH COUNCIL

The formal call of the American Red Cross for the coordination of the country's health activities has been answered by the organization of the National Child Health Council, which has opened national headquarters in Washington, D. C., with Courtenay Dinwiddie as executive secretary. The members organizations are: the American Child Hygiene Association, American Red Cross, Child Health Organization of America, National Child Labor Committee, National Organization for Public Health Nursing, and National Tuberculosis Association.

Two general policies of coordination have been agreed upon: (1) There will be developed a systematic exchange of information on plans of work and itineraries of field workers. Conferences of workers, written reports, and oral discussion of plans by the Executive Secretary with each departmental director will assure the soundest methods of cooperation. (2) It is proposed to establish national advisory committees on such subjects as foods and nutrition, and the health education of school children. It is hoped thereby to avoid the present situation of confusion in the establishment of standards and in the preparation of authoritative statements on large problems of child health. The committees will seek to establish the best possible relationship between national organizations and local and state organizations, and supervise the establishment of standards in general problems of child health.

*See Framingham Monograph No. 5.

ADVISABILITY OF ORGANIZING SPECIAL CLASSES FOR UNUSUAL CHILDREN*

By SISTER KATHARINE, O.S.B., Ph.D., DULUTH, MINN.

RECOGNITION of the existence of different grades of mental aptitude is as old as history. We find reference to the fool in sacred writ, not really in the sense of an imbecile, but connoting the man who lacked judgment and practical common sense. Similar references are found in the writings of Clement of Alexandria and others of the Fathers of the Church, both Greek and Latin. So general was the acceptance of a hierarchy of mental ability that Plato, in his scheme for the organization of an ideal society as outlined in his Republic, proposes that the special aptitude of each individual be determined early in life and that each person be then educated or trained in proportion to his native capacity. His hierarchy, as we may recall, consisted roughly of three tiers. On the lowest level, were the artisans and shopkeepers and those whose end in life was the acquisition of gain; on the second level were the soldiers; on the third and highest plain, the selected individuals who had minds adapted to the contemplation of ideals, as Plato termed them, or what we might term abstract, universal ideas. These were the philosophers and these were the persons who alone were judged capable of governing society, making laws, etc.

We, as teachers, have long been conscious of the fact that in the classes in our institutions and in our parish schools there were very well marked groups, corresponding in the main to Plato's hierarchy. There are present in every class room retarded pupils, technically called backward, moron, and borderline defective; average or normal pupils, constituting about one-half of a healthy class; accelerated pupils, those individuals who could go faster if allowed, but who are compelled to lock step with a system. Some of us have conscientiously spent our time and energy trying to teach the submerged portion; others have taught the middle group because it was the largest and because it represented the mean for the class; others have taught the upper group because results were more easily and more speedily obtained. It is very easy to see that there must be great loss of the pupils' time and the teacher's energy in any arrangement, however ideal, where the units are so diversified.

The results of tests given to more than one hundred thousand children and to more than one and one-half million men in our national army indicate that in an unselected group about one-third are below normal intelligence. This lower one-third would include imbeciles, who have an intelligence quotient below fifty; high and low grade morons; and dullards. The lowest grade of morons and imbeciles should not be found in the class room with normal children. In some states, Minnesota, for example, children with an intelligence quotient of even eighty-five are required to be provided with a special class. The number of persons in the imbecile group is, fortunately, very small and this fact accounts for the appreciably large number of children in the dull, borderline, and rather definitely feeble-minded group. These are the children whom

we would have grouped in one type of special class.

Before considering in some detail the advisability of organizing special classes for this group of children, let us remind ourselves that above this lower third there is a middle third, ranging to intelligence from ninety-five to one hundred five. To this normal third belong the average man and woman whom we meet, the "C" in the army rating, the "C plus" and perhaps "B minus" in our schools. The highest group intellectually is composed of persons with an intelligence quotient varying from one hundred six to one hundred seventy and over. These constitute the "superior folk" intellectually. The number of persons, so far tested, with an intelligence quotient above one hundred forty is only one in about two thousand. More than 30 per cent of all children, however, are above normal in intelligence. We find that mankind distributes itself mentally in accordance with the normal curve of probability.

Figure 1 shows the distribution of intelligence quotients of nine hundred five unselected school children. If we join the upper corners of each of the lines representing in line values the number of persons in each group, we will have a fairly good normal curve with a slight inaccuracy due to the larger number of children in the bright and very bright groups as compared with the dull and borderline groups. As we notice, there are 20.1 per cent of this special series of children in the dull group and 23.1 in the bright group; 8.6 per cent in the very dull or moron

Fig. 1. Distribution of intelligence quotients of 905 unselected children, five to fourteen years of age (Terman).

group; and 9 per cent in the very bright group. While a curve constructed, using the ratings of these school children as a basis, would show a sagging on one side owing to the slightly disproportionate number of bright and very bright children as compared with the dull and borderline, a curve constructed, using the army rating (Fig. II) as a basis, shows, very unfortunately, an opposite tendency, a very great falling off in the number of bright men, C plus, and B men. However, the discrepancy in either line values is not so great as to destroy the working value of the normal curve.

For those of us who are not accustomed to thinking in terms of normal curves, let us say that we are able to arrange people in a normal curve for any trait. Let us take,

*Read before the National Conference of Catholic Charities, Washington, D. C., September, 1920.

for instance, the concept, happiness. If we chart ten thousand unselected persons according to the amount of happiness they possess, profess, or exhibit, we will find that from one-third to one-half of all people would be just

Fig. II. Diagram showing mental levels of the United States Army, as authorized and published under the authority of the surgeon general.

ordinarily happy; a still smaller group would constitute the temperamental optimists; a very much smaller group, the Pollyannas; a very small group, consisting of about $\frac{1}{2}$ of 1 per cent, the exalted paranoiacs whom we find in institutions for the insane. On the other half of the curve, we would place the pessimists, corresponding in number with the optimists; a still smaller number of unfortunates known as melancholians; smallest of all, a group of persons, the suicidal morose, whom we find again in institutions for the insane. If we group persons as to stature, wealth, or any other accidental property or quality, we find the normal curve tendency pronounced.

For a long time we thought that with proper environment in the way of a home of ordinary opportunities, properly prepared teachers, wholesome food, attention to the elimination of such physical defects and weaknesses as were remediable, the mental capacity of most children could be increased to about normal. However, despite the fact that we have better prepared teachers, the beginnings at least of better organized recreations, compulsory education laws, school nurses, and free medical care, the number of retardates remains practically the same. Removal of diseased tonsils, adenoids, etc., attention to decayed teeth, weak eyes, and other physical defects are certainly a help in restoring normal health and possibly in conserving the life of the child; but its mental capacity is quite another factor and this factor remains practically constant throughout life. The superintendent of the Hebrew Orphan Asylum in New York, an institution which houses about seventeen hundred children, remarked recently that it was the experience of the management that "the removal of adenoids and diseased tonsils did not cause a rush of brains to the head." We do not wish to underestimate not only the value but the absolute necessity of proper

medical care, a well balanced, wholesome, and plentiful diet, plenty of fresh air, and abundant opportunities for healthy physical exercise; but when all these matters have been attended to, the child has just his native brain capacity and no more, and it is quite as impossible to obtain from him reasoning processes in excess of his capacity as it is to pour four quarts of water into a two or three quart vessel.

There is very wide variety in the human race, even if we leave out of consideration in this study the two lowest types, congenital idiots and low grade imbeciles. A survey made of persons, 732 in all, who had studied arithmetic during the same time and under practically the same circumstances, reveals some very astonishing findings. About 20 per cent of the group succeeded in working the one hundred problems submitted, correctly; some could not get five. If we consider the children composing the two extremes, how, we may ask, can they be taught efficiently in the same class room? Is not one apt to be either in a state of chronic discouragement or perpetual indifference, depending upon the temperamental bent? Again, let us take the case of

some thirteen year old children whom we can pick out among our friends and pupils. Some of these thirteen year olds have been able to complete the grades and one or two years of high school; others have never been able to complete satisfactorily the work of the third grade. Between these two groups there will be children who complete the eighth grade at fourteen, fifteen, sixteen, or never. While in some cases these facts are due to difference in maturity or difference in opportunity, in a large number of cases the difference is due to native capacity. Absolute achievement is due to environment—educational

Fig. III. Diagram illustrating possibilities of development of children differing in capacity at five years of age. Vertical distances represent mental age; horizontal distances chronological age (Schematic).

opportunities, encouragement, etc. Relative achievement is due to native capacity.

The intelligence quotient or mental brightness of a child can be determined with a very fair degree of accuracy at five or six. Look at Figure III. The horizontal line represents the chronological age of subjects whose intelligence quotient or mental brightness we wish to determine. Mental ages are represented by corresponding divisions on the vertical line. The lowest curved line represents, diagrammatically, a child who was given a mental test at five years of age and who merely succeeded in passing the test at a three year level; he passes the same test at five that normal three year olds would pass. This child is, then, two years retarded at five. He starts to school and progresses—slowly, it is true—but there is progress until the second or even the low third grade is reached. No further mental development will then be possible. This child will likely be pushed along by automatic promotion, making a grade in two years or in three years, but he is simply being kept in school. He is not developing. The third lowest curved line represents a child who is just able to pass the same test at five that other unretarded, mentally normal children pass. His mental age and his chronological age are at the same distance from the vertical and horizontal lines, respectively, at five. This child's development will continue until he has reached the fourteen year level according to the army rating and the sixteen year level according to Terman's

rating, when the nerve and brain structures are developed.

Let us here remind ourselves that the nerve structure is complete at about fourteen, after which time, while new associations can be formed and almost limitless knowledge acquired, no further development is possible. This is true of normal individuals. There seems to be an exception in the case of some selected individuals who at the age of five have a mental age of, let us say, seven or eight (Fig. III, highest curve). There may be development in these cases up to the age of twenty or even higher. However, the mental life and possibilities of development of these unusual children has not been worked out with any degree of surety.

The second lowest line represents a very common type. Here we have a child one year retarded mentally at five—he simply passes a four year test at five. This retardation is serious at that age. The child will make fair progress in school up to the fifth grade. At that stage, work begins to involve the higher mental processes and not simply memory for the most part. He fails regularly. His teachers do not understand him; his life becomes monotonous and dull; he has no interest in work which he does not understand; he drags on for a few years, but he will never be able to complete the work of the eighth grade unless by a system of automatic promotions. Let us recall that 67 per cent of all children leave school without finishing the eighth grade. In administering the Binet test and other mental tests, we have noticed that a very large number of children in the fifth, sixth, and seventh grades will pass the test only at the nine years and eleven

Fig. V. Diagram showing mental status and educational status of children in a school, Columbus, Ohio. For explanation see text. (From an unpublished survey by Pintner.)

Fig. IV. Diagram showing mental status and educational status of thirty-eighth children, Grade VII (a). (After Pintner, Williamson, Va.)

months level. In all cases these children were reported, in after discussions with the teachers, as being slow, sulky, stubborn, unable to study arithmetic, etc. We think the slowness, sulkiness, etc., were in most cases due to the fact that the material as presented was beyond the capacity of the child and that it was the teacher or system that was to blame.

It would be possible for a teacher who is sympathetic and a leader to do no end of good in vocational guidance if she had even a fairly good diagnosis of the mental possibilities of a child. The intelligence quotient of the average man is about 105, or he is at about a fifteen year level, according to Terman. The army rating would place him lower. Pupils with an intelligence quotient of 100 or below should not be encouraged to go beyond the eighth grade. They will fail in the more severe reasoning processes required in the study of mathematics, the natural sciences, and Latin. Of the 10 per cent who attend high school, only 3 per cent graduate. Might it not be possible that a little vocational guidance would lower this educational mortality? Most universities now require an intelligence quotient of 115 or over for admission to the freshman year. Persons with an intelligence quotient of 120 or over will be best for the professions. Tramps were found to have an intelligence quotient of about 85; street car conductors were found to have an intelligence quotient of about 85; sales girls, 84. Every now and then, it is true, there will be found an individual in all of these vocations who has an intelligence quotient of one hundred twenty or over.

We have endeavored to bring into consciousness two facts, the existence of well defined differences of capacity in any group of individuals, provided the group be unselected, and the fact that physical and environmental influences do not increase the native capacity, though both can, if highly unfavorable, prevent the individual's development up to his native capacity.

The underdeveloped child is, then, we are forced to admit, present in every class room of every institution and every parish school. What shall we do with this type of child? Shall we organize special classes or shall we just let this type of child sit in the back seat and drag along from year to year, growing chronologically and physically, but becoming less and not more efficient to cope with conditions in a world of ever increasing complexity—a world into which he must soon enter as a wage earner and in whose merciless service he will at best be tried "as gold in the fire"?

It is astonishing the rapidity with which the movement to compel school boards to organize special classes has grown. There are few states that have not laws excluding the underdeveloped child from the class room of the regular student. We may expect soon to have these laws extended to include all child caring institutions, and eventually all parish schools. To state a few examples of state legislation on this matter, Minnesota was one of the first states to officially recognize the need of special classes. As early as 1915 we find enactments providing for the organization of special classes for the mentally subnormal.¹ The law provides that subnormals be taught in special classes and that their training be under the direct control of the state Superintendent of Public Instruction. All teachers of such classes are to be approved by the said superintendent. " . . . There shall be paid annually out of the current school fund in the state treasury in the month of July to the treasurer of the school district maintaining a school or schools for mental

subnormal children under the charge of one or more teachers whose appointment and qualifications shall be approved by the state superintendent of education, the sum of one hundred dollars (\$100.00) for each mental subnormal child instructed in such school or schools having an annual session of at least nine months during the year next preceding the first day of July."

Arrangement of details as to organization of classes, content of curriculum, qualification of teachers, etc., were left in the hands of the state superintendent of public instruction. The department now provides that the enrollment in these classes shall not exceed fifteen, that only such children as have an intelligence quotient between fifty and eighty-five shall be admitted. Children above eighty-five in intelligence, even if seriously retarded from an age-grade standpoint, shall not be admitted to these special classes; and children below fifty in intelligence are to be sent to the institution for the feeble-minded at Faribault, since they are thought unfit to profit by any instruction that could be given them in these special classes. It is further provided that children suffering from remediable diseases shall have them cared for before being examined for the special class. The Department of Education of the State of Minnesota further provides that "children with mental development between fifty and seventy-five per cent of an average normal child shall be regarded as cases requiring commitment to the State institution at Faribault on their leaving the public schools and shall be so recorded." In view of the fact that many of our retarded children drift sooner or later into these special classes in the public schools, this last clause has special significance.

We think, however, that the laws governing the organization of special classes in Minnesota and the detailed regulations of the superintendent of public instruction under authority of the law have outstanding good features. The state is munificent in its provision of one hundred dollars per year per pupil instructed. The preparation of teachers for these special classes has been ample and the subnormal child in the public school has been well cared for.

New York, as a state, seems to have awakened to the fact that there were children in school who were unfit to profit by the type of instruction given in the ordinary class room somewhat later than Minnesota. The New York legislature² of 1917 provides for the education of children with retarded development. The law requires that the trustees or board of education of each city shall take a census of all children who are three or more years behind grade. Where ten or more children were found to be mentally retarded, special classes were to be provided with instruction adapted to the mental attainments of these children. The legislature of 1918 made detailed provision for the organization of special classes. Two psychologists were engaged by the education department at Albany, and gratuitous aid assured to every town or city wishing to inaugurate the special class movement. Recently a superintendent of a large system in the State of New York remarked that every self-respecting school had now a class for retarded children. He was pleading for the further organization of classes for accelerated children. Special classes for the precocious child are as necessary as provision for those who are retarded in development. If improper methods in the latter case aggravate their maladjustment to life, it must be apparent that much instability in accelerated children can be charged to the attempt to hold them to a line of conduct ill adapted to their needs.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

HUMAN PARASITOLOGY, With Notes on Bacteriology, Mycology, Laboratory Diagnosis, Hematology and Serology. By Damaso Rivas, B.S., Biol., M.S., M.D., Ph.D.¹

To Rivas belongs the well deserved credit of bringing out the first fairly complete English text on Parasitology. The volume possesses many features worth mentioning, chief of which is the omission of the newer and confusing biological nomenclature, which has proved more embarrassing than elucidating.

The author has most completely discussed the subject of parasitology, including protozoan, metazoan, and vegetable parasites and the importance of bacteriology, laboratory diagnosis, hematology, and serology in the various parasitic diseases has been properly emphasized. A valuable chapter on macroscopy and microscopy has been incorporated in the text, which will be found to be of value to many workers in parasitology.

The text is profusely illustrated, though the author can be justly criticized for his selection of illustrations, in that he has used many from other texts. It is to be regretted that more original illustrations were not used or that in making his selection a more expansive source was not consulted. Many illustrations could be improved upon greatly had the author used texts other than those employed. A very valuable light of references added to each chapter greatly enhances the value of the book.

SURGICAL THERAPEUTICS AND OPERATIVE TECHNIQUE. By E. Doyen. Prepared by the author in collaboration with H. Spencer-Browne, M.B., Cantab., etc. Volume III, Regional Surgery (continued). Operations on the abdomen.²

In the third volume, which has recently appeared, we find many of the same attributes which characterized the former two volumes. The work is the work of a genius who, as is common to genius, is apt to lack thoroughness and balance. Certain features are dealt with at great length and in great detail, while other subjects in which Doyen was less interested, but which from the point of view of the general surgeon may be just as important, or even more so, are treated most superficially. The diseases of the rectum, including congenital malformations, hemorrhoids, polypi, malignant tumors of the rectum, fissure in ano, pari-rectal sinus, etc., etc., are treated in about one-third of the space devoted to the discussion of vaginal hysterectomy and vaginal pan-hysterectomy. Doyen describes but one method for each operation, the method he uses; this makes the book interesting and adds a genuine personal touch to its chapters, but herein would lie the danger to the student, for it is doubtful whether many of Doyen's methods would be as successful in the hands of others as they appear to have been in his. His approach for the gall bladder and bile passages by

his chondo-costal incision would probably not meet with hearty approval by the modern surgeon who has successfully performed innumerable gall bladder operations through the more usual and much simpler incisions.

The mature surgeon will enjoy reading Doyen, the young surgeon or the student will find it much more profitable to spend his time on some of the other modern surgical works.

DIABETES. A Handbook for Physicians and Their Patients. By Philip Horowitz, M.D.³

The author has contributed many articles to recent medical literature in support of his theory that diabetes mellitus represents a phase of intestinal auto-intoxication which can be treated by the ingestion of *B. bulgaricus*, provided proper dietary regulations are followed. Most students get as good results without the theory or the therapy of Horowitz. The book is an easily readable summary of present day methods of handling diabetics. It lacks (as do many similar American books) all reference to pioneer work of other investigators—which we believe shows scientific bad taste. It is also to be regretted that a much advertised brand of drinking water receives considerably too much free advertising in the pages of a book of science.

PATIENT'S HANDBOOK ON THE TREATMENT OF DIABETES MELLITUS. By Thomas W. Edgar, M.D.⁴

This is a handbook for patients! If the patient happens to have a literary taste, he might object to some glaring abuses of the English language found in its pages. If he be scientific he might wonder what has happened to Naunyn, to Joslin, to Allen,—diabetics are usually well read; if inquisitive, he will want to know more of the author's serum treatment, and of the nettle infusion which "is evidently of very great value in the treatment of diabetes."

But we doubt if he will really learn enough from the book to justify the addition of such a manual to his library.

A TEXT BOOK OF ORGANIC CHEMISTRY. By A. F. Holleman, Ph.D., F.R.A. Amst. Edited by A. Jamieson O.B.E., Ph.D., F.I.C.⁵

The fifth English edition of Holleman's textbook presents many additions in subject matter over the older issues. The author has allotted additional space to methods which the student of modern organic chemistry must at least know in principle, such as refractometry, viscosity determination and others.

The book of Holleman is so well known and so widely adopted, that criticism of any kind is unnecessary. The book speaks for itself.

AUSTRALASIA.....STERLING & CO
Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

GRUNDBRISS DER HYGIENE UNTER MITWIRKUNG VON ZAHLREICHEN FACHGENOSSEN HERAUSGEGEBEN von Prof. Dr. Med. Hugo Selter. Band I: Allgemeine und sociale Hygiene, die übertragbaren Krankheiten. Band II: Hygiene im Städtebau und in der Wohnung.⁶

To review a work of this calibre in a few words is to do it an injustice. Written by twelve eminent specialists, it is, beyond doubt, the most complete work on hygiene in any language. It is a veritable library on hygiene in all its diversified branches.

Vol. I comprises general and social hygiene as well as communicable diseases. Chapter I contains statistics on birth-rate, illegitimacy, mortality, recruiting statistics, etc. Unfortunately, these are limited to European cities and countries. Chapter II takes up aid in all its phases, as well as climatology, the latter limited to the Eastern Hemisphere. Chapter III, on nutrition and nutriment, is very comprehensive. It includes such subjects as coffee, tea, tobacco, opium and the various alcoholic beverages and the means for curbing alcoholism. Chapter IV is on clothing. Chapter V treats of bodily hygiene through bathing and exercise, takes up the various forms of baths and bathing institutes and, rather minutely, the effect of various exercises on the body and its organs. Chapter VI, on childhood and adolescence, is very thorough, including such subjects as infant mortality (in Germany), school hygiene (including architecture, heating and ventilating systems), etc. Chapter VII takes up industrial hygiene in all its phases; Chapter VIII the prevention of industrial diseases and accidents, as well as the various forms of insurance and the more direct phases of industrial medicine. Chapters IX and X are devoted to communicable diseases.

Volume II is a complete work in itself. It considers human habitations, individual and collective, beginning with the soil and ending with illumination, natural and artificial. The hygiene of city planning is very exhaustively treated, embracing the deleterious effects of cobblestone paving, the disposition of gas-pipes, etc., also such obvious subjects as sewage disposal, water supply, etc. Disposal of garbage and carcasses as well as the disposal of human corpses are treated most thoroughly. The hygiene of dwellings and of hospitals comprises the selection of site, of material and of heating appliances, of architecture, including sound-proofing, ventilation and lighting. To this latter subject an entire chapter is devoted.

It is to be hoped that, ere long, this work will appear in an English translation.

THE NEWER METHODS OF BLOOD AND URINE CHEMISTRY. R. B. H. Gradwohl, M.D., and A. J. Blaivas, St. Louis.⁷

The book is a good compilation of methods used in the laboratory, with discussions as to the interpretation of results. The chapter on basal metabolism is timely and well written, although a more complete description of the portable respiration apparatus might seem desirable.

While the author has included in his new edition the latest methods of blood analysis by O. Folin, he might have safely dropped some of the rather obsolete procedures still contained in the text. The color plates leave much to be desired. Phenolsulphonephthalein and uric acid will produce colors quite different from those shown in the Plate I. A statement like—"Add oxalate to the blood and defibrinate," could have been avoided.

The book as a whole is good and will prove a valuable help to the workers in that field.

MATERNITY BILL FAILS

IN THE final days of the last Congress, the Sheppard-Towner bill which had in different forms passed both the Senate and House, failed to become a law because of the failure of the two houses to agree upon the provisions of a compromise bill. The high hopes expressed by friends of the measure that beginnings on a large scale would be made to educate and aid motherhood have been dashed for the moment, but we feel confident that the defeat is only temporary. The need is too urgent and too appealing to be left unfilled.

While the discussions continued in Congress over the provisions of the bill, the Children's Bureau presented the report on a survey of infant mortality in New Bedford, Mass. The report gives some startling facts in full verification of previous reports. The investigation found that over half of the New Bedford babies lived in sections where families of from fifteen to eighteen, including lodgers, were in many cases crowded together in five room tenements. Practically all the mothers working in the New Bedford mills were in families where the father earned less than the amount necessary to maintain a decent standard of living. Almost half of all the mothers were gainfully employed during the year before the baby was born and two-fifths during the year following the baby's birth. Most of these mothers worked during both periods. Among the babies whose mothers left them to go out to work when the baby was less than four months old, the mortality was nearly twice the average rate.

The low income group showed a high mortality rate, while the group having incomes sufficient to insure proper care and surroundings for the mothers and babies had a low mortality rate. In

the low wage group, twenty babies out of every hundred born alive died before the end of the first year. In the highest wage group only six out of every hundred babies died.

Such facts cannot forever fall upon deaf ears.

SICKNESS SURVEYS

HOUSE to house canvasses to determine the amount of sickness have had considerable vogue during the last three or four years. The results of these surveys have been generally accepted without consideration of their limitations.

The first limitation is that the evidence is based upon what is told by the persons questioned. It is a self-diagnosis reported to non-medical canvassers. There are no means of checking up the facts. Such canvasses include old and young and all of the chronic malingerers; they do not include those who are really disabled but who are at work. When the memory of people is relied upon for the illnesses of the previous year, the unreliability of the statistics must be obvious.

Even supposing the canvassers could secure reasonably correct information, there still remains the difficulty of selecting a time for the canvass when the conditions are typical. The mortality statistics for 1919 indicate more than twice as many deaths in January as in September. The studies of morbidity in insured groups made by the United States Public Health Service indicate that sickness is four times as prevalent in certain seasons as in others. These facts make it plain that a survey in the summer months will not give an accurate picture of the health of the community any more than would a similar survey in January or February.

Accurate statistics of disabling sickness can be obtained only through the study of insured groups

where there is adequate check to determine the validity of sickness claims. But even here the figures can be made of general application only if the groups from which they are taken are all inclusive and not selective.

EYESIGHT AND EFFICIENCY

WE PRESENT in this issue a comprehensive review of recent authorities on hygiene of the eye, as it relates to the efficiency of children in schools, workers in industry, and people generally; its reading cannot but impress one with the vast range of problems which are yet to be solved in school and industry and public places, in the attempt to realize the ideal of "daylight lighting."

The author states in summary, "The amount, quality and distribution of light in schools, libraries, factories, etc., should be carefully regulated; at present such buildings are poorly illuminated." The author quotes further from authorities that "Ophthalmologists should carry out investigations in estimating the effects of errors of refraction, errors of muscle balance, defective illumination, and so on, on the fatigue of the workers in different processes of various industries."

Attention is called to the fact that visibility, legibility, and eye saving characteristics of printing are generally overlooked. He quotes from Surgeon General Braisted, "If fine print could be officially stigmatized as a menace to eyesight; if the Federal government were to forbid transmission through the mails of children's school books improperly printed, we would have a ready solution of the problem."

Special methods of lighting for industry, the use of protective glasses, myopia and education, the supervision of school children, the care of the eyes in nursery children, ophthalmology in programs of child hygiene, the conservation of vision, the prevention of blindness and of trachoma, are some of the subjects reviewed in this summary of a subject the importance of which increases in the public mind at a rapid rate.

ABOLISHING PROGRESS

THE *Boston Transcript* comments editorially upon a proposal of the State Board of Control of Vermont, in which the *Transcript* states, "The Vermont legislature is asked to vote for the repeal of progress," for if the report of the Board were adopted "it would evince a determination to wipe the twentieth century out of human experience and by some legislative magic to put the state back into the nineteenth or even the eighteenth." After citing the proposal to repeal all laws that support activities that are paternalistic in their nature, such as forestry, boards of examination

and regulation, associations that promote special interests of agriculturists and other producers, investigations of water supply, the work of the Department of Agriculture against bovine tuberculosis, creamery inspection, etc., a large part of the appropriation for education, the Board goes on to state that they favor a return to such public health system as may have existed in former days. The *Transcript* adds that "the report may be regarded as an example of the remarkable productions which sometimes find their way into legislative halls rather than as cause for alarm for the future progress and prosperity of the neighboring state." The editorial states that the document suggests the "vagaries of the Chestertonian intellect" because it leaves in the minds of the readers a question as to how much of it is really meant by the Board, "who think they are to be taken with entire seriousness in asking Vermont to obliterate the twentieth century."

PERSPECTIVES IN HEALTH WORK

CONSIDERABLE attention is regularly given in the newspaper press to the manifestations of unusual diseases. Reports of unusual diseases frequently become front page material. The medical press often reflects the interest of the public in such diseases and medical research gives time to their investigation all out of proportion to the importance of the subject.

That such diseases have a spectacular interest one cannot doubt: that is the reason why the public press features them. But the annual report of the Mortality Statistics coldly places them in their proper position in the health movement. It is well that this is done; otherwise, we should have a distorted view of the public health needs. The examination of the causes of death usually tends to bring the emphasis of study and publicity where it properly belongs.

The statistics of mortality recently published by the Census Bureau for 1919 show that in the registration area there were 1,096,436 deaths. Of these deaths, heart disease caused 111,579, pneumonia 105,213, tuberculosis of the lungs 94,772, influenza 84,113, acute nephritis and Bright's disease 75,005, cancer and malignant tumor 68,551, violent deaths 67,674, cerebral hemorrhage and softening 66,918, diarrhea and enteritis 37,635, bronchitis 10,913, diabetes 12,683, diphtheria and croup 12,551, appendicitis and typhlitis 10,029. These figures show that more than 70 per cent of all the deaths came from the causes mentioned. The emphasis of medical study and publicity should, therefore, be turned to the organization of work for the prevention and cure of these diseases which are taking such a heavy toll.

PHYSICAL RESTORATION IN THE REHABILITATION OF DISABLED PERSONS*

BY WILLIAM T. CROSS, SURVEY OFFICER, STATE DEPARTMENT OF PUBLIC WELFARE, CHICAGO, ILL.

“**A** PHYSICALLY handicapped person,” according to the Illinois law, “shall mean any person who, by reason of a physical defect or infirmity, whether congenital or acquired by accident, injury or disease, is, or may be expected to be, incapacitated for remunerative occupation.” This definition of physical handicap is used also in the Federal (Fess-Kenyon) Act. It is noteworthy for its description of a person’s physical condition in terms of occupational efficiency. “Rehabilitation,” according to the Illinois act, “shall mean the rendering of a person physically handicapped, fit to engage in a remunerative occupation.” The law provides for placement of disabled persons in industry, as the final step in the process of rehabilitation. The more important services provided in the Illinois law are: (1) Acquiring information concerning persons who may be physically handicapped. (2) Arrangement for such therapeutic treatment as may be necessary for rehabilitation. (3) Procuring and furnishing at cost artificial appliances. (4) Arrangement for vocational training, including payment of maintenance for twenty weeks at ten dollars a week, and subsequent placement in industry. (5) Arrangement for social service and advice in the home.

Child Labor and Injury

Oliver Sleszynski was nineteen years old at the time of his operation in January, 1920. He was an illiterate Polish boy. He had started to work in the mines almost as soon as he could lift a pick. In May, 1917, a mine explosion crushed his left leg. It was amputated in the middle of the thigh, and he was in the hospital for six months. He was discharged with the stump healed, except for a small discharging sinus which the surgeon told him would heal shortly. He was not fitted with an artificial leg.

He received \$1,900 compensation. This money was turned over to his father and step-mother and, with only a few dollars in his pocket, Oliver came to Chicago, where a sister was living. Failing to locate his sister, he secured lodgings in a cheap hotel and for three weeks vainly sought employment. Other cripples stayed at this hotel and they obtained their living by begging. It is the practice for such persons to procure licenses to sell shoe strings or other merchandise, which they display only when a policeman is in sight. Oliver, despondent and moneyless, was about to procure his license when someone told him of a society engaged in rehabilitation work.

This society sent him to a hospital for examination. It was found that the sinus on the end of his stump had never healed. A reamputation was performed, removing four inches more of the thigh. After eight weeks of hospital residence, he was measured for an artificial limb and in two more weeks he was able to walk about without crutches or cane. During his stay at the hospital, Oliver was taught English and tried his hand at several kinds of occupations. He was anxious to learn photography and to become a motion picture operator. Books on the subject were procured and many of his English lessons were taken from these books. When he was ready to leave the hospital, a job was found with a motion picture concern, developing films at night. For this he received five dollars a night. In the afternoons he

This rowing machine for developing withered limbs is a part of the equipment of the Spaulding School for Crippled Children, Chicago. The School, maintained by the Board of Education, accommodates about three hundred day pupils.

continued his study of English and took up other subjects. His pay was raised and, recently when the concern closed down, Oliver secured an excellent job at the same business at Kansas City.

Oliver Sleszynski presented a problem of rehabilitation from the day he was injured. The way to reconstruction was made harder for him by his illiteracy, by the lack of industrial opportunities in the mining community, and by parental estrangement. The compensation allowance was not used for his rehabilitation and he was discharged from medical oversight without an artificial leg and with an unhealed stump that eventually required reamputation. To an already difficult task of reconstruction was added the discouragement that followed incomplete surgical attention.

It has been estimated on the basis of community censuses made during the recent survey that

*The data contained in this article are taken from the results of a survey relating to the rehabilitation of physically handicapped persons in Illinois, given in part in the Report of the Director of Public Welfare, State of Illinois, 1919-20.

from 1 to 1.5 per cent of the population of Illinois cities are physically handicapped. In every community of several thousand population are to be found many persons whose physical disabilities interfere with remunerative occupation. The

These children at the Spaulding School are taking lessons in cobbling for the therapeutic value of the work.

problems of reconstruction which they present vary almost as widely as the number of persons, for in each instance the individual's attitude, the nature of his disability, and the time in his life when it occurred, his education and training, his home situation, and the variety of occupations in the community are to be considered.

In one village, for example, twenty-five seriously injured coal miners were visited. They had all become disabled within a year. They constituted by no means all the disabled inhabitants of the town, yet they were more than 1 per cent of the population. There is little chance for good surgical diagnosis and treatment in the place. Nineteen of the men are unemployed at the pres-

Weaving is particularly adapted to the needs of certain of these handicapped individuals. It affords the necessary interest and activity without undue strain, while providing a means of self-support.

ent time, and twenty-three understand no other occupation; fourteen of the twenty-five do not read or write English. The community does not afford a variety of occupations or much chance for learning new trades. There are no well developed welfare agencies.

Medical Agencies Surveyed

Special inquiry has been made concerning the number of physically handicapped persons discharged from hospitals in Illinois. For twenty-nine general hospitals with a total bed capacity of 5,596, it is estimated by superintendents that 2,405 persons were discharged last year with handicapping disabilities. Estimating on this basis for institutions not replying, it appears that approximately 7,500 persons are discharged from general hospitals in Illinois annually with handicapping disabilities. Four-fifths of the number of cases reported by the twenty-nine hospitals were from five of the larger institutions. Cook County Hospital, Chicago, reported 1,042, not including surgical cases. Even though the figures given in most instances are estimates, and no common rule could be applied as to the seriousness of the handicap, it is probable that the number of physically handicapped persons known to hospitals, dispensaries and other medical agencies is greater than the number that may be reported through any other channel.

Passive exercises to develop useless members are employed at the Spaulding School for Crippled Children. The school provides the best medical and surgical care, in conjunction with standard instruction.

A special study was made of 178 cases on the medical and surgical wards of St. Luke's and Cook County Hospitals, Chicago. About one-third were found to be in need of industrial rehabilitation, or special occupational readjustment. A large percentage of the men needed rehabilitation. In most instances the men appeared not to have considered their future possibilities and had no suggestions to offer as to kinds of work for which they might be fitted.

A comparatively small group among the women were in need of rehabilitation. A striking case was that of a well educated elderly woman suffering with tuberculous spine and lupus on the face and neck. On recovering she will be frightfully disfigured. She has been a governess all her life.

More were found to be permanently disabled on the medical wards than on the surgical wards. Chronic heart cases were found to have returned

in some instances many times, the lack of success in treatment being due chiefly to inability of the physician to control the occupation and mode of living after discharge.

In the replies received from 101 hospitals in the state, only nineteen indicated that they had physiotherapeutic apparatus, and only four of these reported organization and staff for occupational therapy. Fourteen hospitals in Illinois are known to have organization and staff for social service in the home.

In organizing for rehabilitation of patients after discharge it would be of assistance for hospitals to record in every case the physicians' prognosis in respect to physical handicap, and in cases of serious disability his statement of specific types of occupation in which the individual may or may not become engaged. Another important step would be the adoption in all hospitals not now having them, of up to date therapeutic equipment

Work for the shut-in. An orphan girl in a poor home, victimized by spastic paralysis, trained by the Vocational Society for Shut-Ins. Her hands are becoming pliable, and she is losing her invalid introspection.

and methods. For Canadian military hospitals it is reported that at least 50 per cent of all hospital populations have required and received some kind of physiotherapeutic treatment. In addition to these provisions, every hospital that undertakes to do as much as possible toward re-establishment of patients after discharge will require

a social service department or, in case of the smaller institutions, a system of referring patients to standard social service organizations.

Industry and Insurance

What the employer may do toward the physical and occupational restoration of workmen is illustrated by the following case:

Mr. Schmidt, 35 years old, American born, had been suffering from arthritis, and was unable to continue his work as box maker for a garter company. His wife also worked in the garter factory. The fourteen year old son was at work and assistance was given by relatives.

Competent medical care improved Mr. Schmidt's condition. The factory's interest was aroused, and he was supplied with home work. During this time Mrs. Schmidt broke down under the nervous strain. It was later discovered that a part of her trouble was due to her posture at work. Her job was changed, and work limited to half a day—the factory supplementing her wages.

When Mr. Schmidt was able to earn \$17.00 a week on home work, effort was made to replace him in industry.

The economic re-establishment of Mr. Schmidt and his family grew out of the interest of the

employer in his and his wife's working conditions. Where only a few employees are involved, the solution lies in the personal interest of the management; but where many disabled persons are to be employed, systematic supervision by the medical department of the industry is necessary.

Tapping machine operator. Harvard Electric Company. This man lost his sight, but not his job, as the Chicago Lighthouse trained him to continue to earn his living at the old job by touch.

This includes control of transfers from one job to another and preferential assignment of persons with specified types of disability to certain jobs. The use of standard job analyses in placement of physically handicapped persons has been studied in the present survey. These job descriptions would be of more assistance if with each job were checked the specific disabilities which would not interfere with performance of the work, as agreed upon by the medical department of the concern.

That only able bodied workmen could be used in their plants was found to be the attitude of a number of employers or foremen interviewed; but in nearly every plant disabled workmen were seen. Analyses were made of ninety-two different jobs in twenty-three representative industries and it was found that at least 9 per cent of the employees in these plants were engaged at work that might be performed by disabled persons. Some disabilities, such as defective hearing, hernia or amputation of one leg, were found to interfere very little with work in these manufacturing

establishments, whereas opportunities for the blind or for one armed men were comparatively rare.

In sending a man whose physical capacities are understood to a task whose physical requirements

Workshop of the Service League for the Handicapped, Chicago. are known, and in safeguarding the processes of promotion and transfer, room is made for the employment of an indefinitely large number of physically handicapped persons and a barrier is erected against the occurrence of accidents and disease. The improvement of medical service, especially of a preventive nature, tends to establish a better relationship between man and job. One Illinois concern with a pay roll of six thousand persons is found to have a well equipped department of physiotherapy in its medical division. To the customary functions of medical departments, of examining employees and of sanitary inspection, might be added the functions of refitting injured employees for work in the plant and of supervising the employment and promotion of disabled men.

The Matter of Re-employment

A study has been made of the circumstances of re-employment of 2,089 persons seriously injured at work during the year 1919. Two-thirds of these were re-employed by the same concern, at least for a short time, 75 per cent of them being put back at their former jobs. Young men were more frequently retrained by their former employers than older ones, and scarcely any systematic retraining was given.

Through the cooperation of industrial concerns, of insurance companies, and of the state in the administration of the Compensation Act, it is apparently possible to accomplish a great deal toward the physical and industrial re-establishment of disabled persons. The State Rehabilitation

Bureau in New Jersey, working with the Industrial Commission, is reported to have reduced the amount of settlements for total permanent disabilities in 90 per cent of the cases they have handled. Some improvements are to be made through the amendment of compensation acts. In Illinois, for example, prosthetic appliances are not required as a feature of medical treatment and they are rarely furnished. The case of Oliver Sleszynski, described at the beginning of this article, is an example. Many persons who are severely injured make settlements with their employers before the exact nature of their injuries is known. Following settlement, they fail to secure such surgical, medical, or physiotherapeutic treatment as may be needed to restore function in the injured part of the body. The Compensation Act, which now allows early settlement in many instances to the detriment of the injured person's physical rehabilitation, could be made to favor the man's restoration by providing that no final settlement shall be entered into until the employing organization has shown, by competent medical testimony, that no further improvement can be expected from medical or surgical treatment.

Educational Agencies Contribute

Approximately one-half of all handicapping disabilities are found to have occurred before sixteen years of age. The problem of reconstruction for children is especially the concern of the physician, the school board and welfare agencies. Of 52,171 examinations of children between fourteen and sixteen years of age, for work certificates in Chicago last year, nearly one-third were found to have physical defects of such seriousness as to require withholding

Boy of twelve, born without arms, who learned to write by holding pencil between his cheek and right shoulder. Recently by a skillful operation he has been provided with artificial arms, and is developing talent as a cartoonist.

certificates. The following case is an example:

John, an Italian boy, came with his mother to procure a work certificate shortly after his fourteenth birthday. He was extremely thin, and had a decided outward curvature of the spine, presumably from an early tuberculous condition. The mother was prematurely aged and nearly blind from trachoma. The father and an older brother worked, but the family felt that John had now reached an age when he should contribute.

John was not allowed to work. He was fitted out with clothing and books and induced to return to school. The mother was sent where she would receive treatment for her eyes. Later in the year, when Arden Shore Camp was organized, John was sent there. He did not improve

much at first and a bursitis of the knee developed. His tonsils were removed, and he improved more rapidly. During the time while he was in the hospital, he wrote one of the vocational guidance staff a letter which indicated literary ability.

After John's physical condition had been built up he came home and was sent back to school. He thought he would like to become a printer, but learned that his handicap would probably bar him from this occupation. He was encouraged to go ahead in school, with the idea of becoming a proofreader, or of preparing for a secretarial position. A scholarship from a fund provided by the Vocational Supervision League was secured and John was returned to school.

However, the family persist in the idea that this fourteen year old cripple should contribute to the family purse.

Many defects discovered in later childhood have gone with little or no attention since infancy. Of 2,046 crippled children under 15 years of age included in the Cleveland survey, 68 per cent were found to have been disabled under 5 years of age.

In addition to the problem of proper medical attention, children with serious disabilities are handicapped through difficulty of securing standard education, school facilities being poorly adapted to their needs. In some instances they are backward mentally. In a study of 316 children in the Spaulding School for Cripples, Chicago, 84 per cent are found to be retarded, the average retardation of these being 2.5 grades.

The periodic examination of school children for physical defects, and the maintenance of a continuous record of all children from the time they enter school until they leave it, is an essential provision in getting at the problem of the disabled child. It is desirable also to maintain a complete list of all defective children not in school. The maintenance of special schools for cripples, such as the Spaulding School in Chicago, as a part of the regular school system, yet with facilities for nutritional, surgical, and physiotherapeutic treatment, is necessary if the physically defective child is to be given an equal chance with the able bodied. Of the same importance are special classes for the anemic, the blind and semi-blind, the deaf and hard of hearing, and children with defective speech, such as are authorized by law in Illinois. Under the British Education Act, boards of education are authorized under exceptional circumstances to make any provision, including board and lodging, "which they think best suited for the purpose of enabling . . . children to receive the benefit of efficient elementary education." Local education authorities are required to pay for physically defective children in suitable hospital schools, where they exist; and in case none have been established, to provide them before March, 1927. Local boards are, in addition, given supervision over the working conditions of children.

If the viewpoint of economic rehabilitation of the disabled person—man, woman or child—is maintained from the point of initial diagnosis to the point of ultimate adjustment at remunerative

Community Clinic for Crippled Children at Decatur, Illinois, conducted by the local chapter of the American Red Cross.

occupation, delays, discouragements and poverty are reduced.

A young man at 28 years of age was found to have been suffering from the results of infantile paralysis for six years. He had been supported during the time from the earnings of two younger sisters. He was housebound and could think of little profitable employment. In trying to find a cure he was under treatment of doctors of medicine, osteopaths chiropractors, spiritualism, baths, a "bone-setter," and "sure cures." After he had spent five hundred dollars, an appeal for financial aid to buy a violet ray outfit brought him to the attention of a visiting nurse. An orthopedic surgeon was called in and muscle training was given. With the help of braces and crutches he is expected to be able to walk and thus improve both his outlook on life and his opportunities for gainful employment.

This young man's difficulties seem to have been due somewhat to his poor choice of medical advice. Another example indicates that discouragement may arise also where advisers are numerous:

In 1915 John Sanderson suffered a contusion of the foot. He had been injured while employed as a laundry worker. During the following four years he was taken care of by five hospitals, two dispensaries and twenty-two doctors. The foot did not heal and a tuberculous ankle developed. The industrial concern sent Sanderson to three different hospitals and seven doctors. The man himself went to four doctors in search of relief. Various social agencies sent him to one hospital, to three dispensaries and to eight doctors. The man's condition is unimproved and he has lost confidence in agencies that seek to help him. His resources have been exhausted and his compensation has been reduced.

Had a plan of rehabilitation for John Sanderson been agreed upon five years ago, when he was injured, and had the idea of reconstruction been "sold" to him in a practical way, his subsequent history might have been different. What was

needed for his re-establishment was not so much a new type of service, as the concentration and effective use of existing facilities.

For the assistance of medical agencies and practitioners, and of welfare organizations in carrying through a plan of re-establishment of disabled persons, it may be found desirable to appoint aids, under the Rehabilitation Act, to keep in touch with individual cases. These workers would be prepared especially to deal with problems of vocational training and employment. They would cooperate with medical and social service staffs of hospitals and with the medical and employment departments of industrial concerns. For a limited number of cases it is suggested that a rehabilitation hospital be established at Chicago, as a part of the central group of hospitals under the joint supervision of the Department of Public Welfare and the University of Illinois.

NOW COMES THE X-RAY AMBULANCE

THE efficacy of health service is largely a matter of the distribution of the attention, which accounts for the fact that the latest developments of science are effective only here and there, and even at best are employed spasmodically.

The great research centers maintain standards of service and employ methods of procedure quite impossible to utilize in more remote districts, so that the clinic and hospital of the city becomes the Mecca of all who suffer from complicated or obscure conditions.

But not all who need such service can travel, and even those not far removed from the best equipped clinic may in a crisis find it impossible to be transported to a point where x-ray diagnosis, for instance, can clear up an obscure condition.

Perhaps no service in the British armies was more effective in bringing about proper corrective measures without undue delay than the mobile x-ray units. The bones set so that approximation of the broken parts was accomplished directly under the eye instead of being left

International
The x-ray ambulance makes it possible to take photographs at the home of a patient too ill to be moved. The service is directed by the Red Cross Society under the supervision of the Lady Theodora Davidson.

more or less to guess work without the aid of the ray, and, in the severe cases, prompt instead of delayed treatment, resulted in good end results in many cases that would have suffered more pain and greater deformity under other conditions.

It is inconceivable that methods found so efficacious, and withal so humane, during the war should fall into disuse and the war discoveries of science not be made effectual for the citizen populations of the world.

We are carrying nursing service direct to the people, and dietary management, and visiting housekeeping. The portable x-ray is a logical development of a public health consciousness that will not leave one stone unturned that can be made to contribute to the greatest service to the greatest number. Still further improvements are to be looked for in the way of new departures of this kind.

S. P. M.

ACCIDENTS TO WORKING CHILDREN

In an article by Miss Lucile Eaves, director of research, Women's Education and Industrial Union, Boston, in the *American Child*, analysis is made of one thousand industrial accidents suffered by Massachusetts children fourteen and fifteen years old. In dealing with the causes of the accidents reported, Miss Eaves says, "The awkwardness of children of the adolescent age, particularly of the boys, proves that they have not learned to direct perfectly the activities of their own bodies, so their inability to control the additional forces represented by machines and tools is not surprising." The frequency of accidents to children, charged to horse play and fooling, or deliberate violation of safety regulations, raises questions about the possibility of making factories safe places of employment for immature and irresponsible young people.

FINED FOR HOUSING RATS

Anyone in London discovered harboring a rat or a mouse in his house is liable to a penalty of £5, under a law recently enacted in Parliament. If the "offense" is continued, he may be fined £20. Health measures demand the extermination of rats, as they maintain an efficient transportation system for "black death" and other plague germs and constitute a real hazard against lives and property. A recent bulletin from Washington makes the statement that it keeps 200,000 men working full time to support the rat population in the United States.

International

A civil mobile x-ray unit has been installed by the British Red Cross Society whereby the patient at home, too sick to be moved, may have the advantage of x-ray diagnosis. The wire lead, transmitting the electric power, is carried directly into the sick room.

HYGIENE OF THE EYE

BY JOHN GREEN, JR., M.D., St. Louis, Mo.

IN HIS treatise on "Preventive Ophthalmology" Parsons¹ says that the objects of preventive ophthalmology are:

(1) The prevention of damage to the individual: (a) prevention of damage to the eyes from accidents, deleterious radiations, defective illumination, organisms, etc.; and (b) prevention of damage to health from accidents, headaches, fatigue, etc.

He calls attention to the loss of time and money by preventable accidents to eyes. Workmen are still loath to wear goggles, which are now generally provided free of charge by employers, and suggests as a means of increasing their use that the latter be relieved of all liability if accidents occur when the workman is not wearing his goggles. "Safety first" propaganda and the efforts of welfare workers are needed to dissipate the suspicion of work people that preventive measures are not solely for their own benefit.

Investigations Were Called For

He discusses the deleterious action of ultraviolet radiation on the eyes. Infra-red (heat rays) may also have a potent effect which is important in view of the high temperatures employed in many industries.

The amount, quality and distribution of light in schools, libraries, factories, etc., should be carefully regulated; at present such buildings are usually poorly illuminated.

Ophthalmologists should carry out investigations "in estimating the effects of errors of refraction, errors of muscle balance, defective illumination, and so on, on the fatigue of workers in the different processes of various industries."

The examination of the eyes of school children and testing should only be intrusted to qualified men, those who have had actual experience in clinics, etc., and, to this end, he suggests the establishment of ophthalmic centers in various parts of the country.

(2) The prevention of damage to other people: (a) Regulations for the prevention or transference of contagious diseases; (b) regulations for the Public Service, Navy, Army, air forces, mercantile marine, railways, motor industry, movies, etc.

Recently there has been formed the Council of British Ophthalmologists: men chosen by the representative ophthalmic organizations of the

United Kingdom. This body acts in an advisory capacity to the public services. The Council, in operation only a year, has issued a report on the lighting of test types, and on the teaching of ophthalmology to medical students and has been asked to appoint representatives to serve on a committee to assist the London County Council in dealing with the lighting of moving picture shows. Among the functions of the Council will be fixing standards of vision, color vision, fields of vision, vision under low illumination, and ability to judge distances with accuracy.

Parsons states that too little attention has been paid to good printing—its visibility, legibility, and eye saving characteristics. Erdman and Dodge, psychologists, Cohn and Javal have investigated the subject; but the sole practical outcome has been some improvement in school books for young children. The world famed printers have been guided by canons of art and not by rules of service. We know little about the physiology and psychology of reading and writing, and the sooner we set to work to learn, the better it will be.

In the printing of music, the unit of visibility is the accidental sharp, flat, or natural. The violinist's notes should be larger because he has to read them twice as far away as the pianist.

In regard to compensation for disability, Parsons states that decisions are rendered in the courts resulting in wide variation in awards for practically identical disabilities. The vast majority of disabilities can be codified on a percentage basis.

New Methods of Lighting

A new method of producing "artificial daylight" makes use of a colored and curiously patterned reflector for correcting the distribution of energy in the spectrum of a lamp. The distribution of colors was calculated on spectro-photometric measurements of opaque pigments made by means of Sir William Abney's color-patch apparatus. The reflector is designed to produce a daylight effect from a tungsten filament half-watt lamp. The inventor, Mr. L. C. Martin,² demonstrated his appliance at a meeting of the Illuminating Engineering Society and showed the difference between the corrected and the uncorrected light in the effect produced upon a number of colored materials. Under ordinary illuminants blue appears low in luminosity compared with red, but

1. Parsons, J. H.: *Preventive Ophthalmology*, Oxford Ophth. Cong., 1919, Trans. Ophth. Sec., United Kingdom, xxxix, 269.

2. Martin, L. C.: *Artificial Daylight*, Brit. J. Ophth., iv., 332.

with a lamp having the corrected reflector the two colors, blue and red, are not very far removed from one another in luminosity.

The problem of artificial daylight³ is one of importance in many industries. In the earlier methods transmission through tinted screens was employed. An apparatus, the result of the combined work of a physicist, Martin, an artist, Sheringham, and an expert on camouflage problems, Major Klein, and known as the "Sheringham daylight" has recently been perfected. It attempts to solve the problem by the use of carefully combined color reflectors. It is difficult to define daylight, on account of its great variability. Commenting on this point, the editor of the *Illuminating Engineer* for February, 1920, says: "In order that the whole subject may be placed upon a scientific footing, it appears essential that a standard of 'normal' daylight should be definite and the degree of accuracy with which 'artificial daylight' units for various purposes should approach this standard specified." He also points out the necessity for a standard white surface and a standard nomenclature of color-tints.

The work reported on by Luckiesh⁴ was prompted by the recently developed opinion that eyeglasses, especially in the industries, should not transmit infra-red radiation. The data presented in this paper do not directly reach the root of the problem, but they are of considerable importance. Energy quantities and densities in the eye media are established and should aid the physiologist who is interested in the question. This paper is confined purely to the physical aspects of spectral energy distribution in illuminants, of the absorption by the eye media, of optical laws, of luminous efficiency of illuminants, etc. The best glass to keep out the short wave chemical rays that induce conjunctivitis, etc., while interfering least with vision is, according to Larsen,⁵ yellow glass, (No. 23 Nitsche and Guenther scale). This absorbs 25 per cent of the 580 wave rays; 50 per cent of the 520 rays; and 85 per cent of the 460 rays. The yellow tint is comfortable and impairs vision very little. He adds that the macula is protected with yellow pigment in the retina, another physiologic argument in favor of yellow glass.

There is a prevalent belief that the kerosene flame possesses advantages for the eye not had by other illuminants. A former paper by the authors, Ferree and Rand,⁶ recounted results comparative of the effect of certain filament lamps on the power of the eye to sustain clear and comfortable seeing.

In the work of the present paper, the comparative testing was continued. Using Welsbach gas mantles of different proportions of ceria and thoria, the results obtained were again compared with those derived with the kerosene flame.

By changing the proportions of ceria and thoria in the Welsbach mantle, a light can be obtained with its dominant color ranging from blue green through green, yellowish green, clear yellow, and orange. The maximum candle power is obtained around 0.75 per cent ceria and 99.25 per cent thoria. The light from this mantle is an unsaturated yellowish green. With an increase in ceria the dominant color shifts towards that of the long wave lengths; with a decrease of ceria toward that of the short wave lengths. One table shows the tendency of the different illuminants to cause loss of visual efficiency; another gives a comparison of the tendency of the different illuminants to cause loss of visual efficiency or power to sustain clear seeing and to produce ocular discomfort. The paper is highly technical and cannot be satisfactorily abstracted.

Protective Glasses

In an editorial in the *American Journal of Physiological Optics*⁷ it is stated that recent investigations have shown that light neutral tints and shades of red and yellow glasses do not markedly influence the absorption of the infra-red, but that glasses which are strongly absorptive in the long wave length region of the visible spectrum are more pronounced and efficient absorbers of infra-red radiation.

Increased temperature decreases the transmission factor in every case except in light blue glass. Data are given by Coblenz and Emerson⁸ to show that the infra-red rays (heat rays) emitted by a furnace heated to 1,000 degrees or 1,100 degrees C.: (1) about 99 per cent is obstructed by "gold plated" glasses; (2) about 95 per cent by sage green or bluish-green glasses; (3) about 60 to 80 per cent by black glasses; and (4) about 60 per cent by greenish yellow glasses. At higher temperatures these data would be somewhat different.

Berry⁹ speaks of the proposed safety code requiring employees to furnish goggles and making it a condition of employment that an employee wear such goggles.

There are 200,000 eye accidents in the industries every year. Industrial processes in which protection is needed for the head or eyes of workers include chipping, riveting, babbitting, scaling,

grinding, sandblasting, high temperature welding, open-hearth and blast furnace work, electrical operations, and processes involving harmful fumes. One may also note burns from caustics, fragments from mushroomed tools, and glass blowers' cataract.

Goggles should have non-corrosive frames which will withstand sterilization and must be submitted to a "drop" and "heat" test.

In his presidential address before the American Medical Association, April, 1920, Surgeon General Braisted¹⁰ discussed "Causes of Eye Strain in Children." He notes that a large proportion of the text of school books is in fine print; much is set up in six point type. "No child of ten or under should have to study a book printed in anything smaller than twelve point lower case, or eight point capitals; and older children should not have to con by the hour a type finer than ten point. If fine print could be officially stigmatized as a menace to eyesight; if the federal government were to forbid the transmission through the mails of children's school books improperly printed, we would have a ready solution of the problem. Left to the example of the individual school or to the individual state, the correction of an evil of this kind will not be achieved for many, many years.

The strike of printers in 1919 compelled many magazines to suspend publication. Others, more resourceful, issued numbers printed directly from photo-tint plates from typewritten copy. Wuerdemann¹¹ noted in this copy a lessened legibility, largely due to the difficulty of instantaneous recognition of the word symbols, made up of letters. The easiest face of type to read is one in which the vertical lines are more accentuated than the horizontals; in ordinary type of the typewriter, the horizontal components are of about the same weight as the verticals. When magnified, the typewritten copy will be seen not to have the clear definition of the lead type print. If, however, clear copy of type to which we are accustomed be thus reproduced, a satisfactory easily read page may be made.

Myopia and Education

A very interesting discussion of myopia and its relation to education took place at the 1919 meeting of the Ophthalmological Society of the United Kingdom. Harman¹² discussed children whose eyes are immature, defective, or blind.

(1) *Immature*: Strain, illness, or a toxic condition interferes with the functions of the eyes; in early years the instability of accommodation

and binocular vision is notorious; and this instability must extend to other functions of the eyes and to the fabric of the eye itself. In a young child "the eyes feel fatigue in proportion to the mental exertion needed to recognize the meaning of the object presented to the eye."

Set lessons in the infant's class are commendably brief in comparison to the time allotted to action, lessons, or games. The allotment of time has been made with a view to the supposed needs of the average child. A child, taken into the school at four—earlier than in the United States—does not have his ocular examination until seven. This is surely a most unscientific procedure. One might almost stigmatize it as inconceivable.

Harman examined under homatropin the eyes of 368 young children in breeding and nurture above the average. These were divided into:

Group I, or Average Eyes:

Emmetropes, or H less than 2D.

As less than .5D + H less than 2D.

Total, 236 = 65.1 per cent.

Group II, or Imperfect Eyes:

H over 2D.

As. less than .5D + H less than 2D.

H more than 2D with As.

Myopes.

Cataract cases.

Total, 126 = 34.9 per cent.

"This means that one in every three children is not fit to do ordinary school work under ordinary conditions." He concludes that our present methods of submitting infants to the work of school life without any attempt to ascertain their fitness for the work is wholly unscientific. He would grade young children according to sight as follows:

Grade I. Fit for the regular curriculum.

Grade II. For "easy treatment" as regards eye work and extended observation.

Grade III. For glasses and "easy treatment," i. e., using educational methods similar to methods employed for the semi-sighted.

(2) *Defective*.—In 1907 the first "Myope" classes were started. There are now twenty-one in London alone. The children in these classes show congenital defects in 7.02 per cent; damaged eyes from inflammation in 30.35 per cent; and myopia in 62.62 per cent.

The scheme of teaching is as follows: (1) Oral teaching with normal children. (2) Writing on blackboards with chalk, free arm fashion. "Printing" of books on large paper sheets, using rubber faced types. (3) Handicraft that will develop attention, method, and skill with the minimum use of the eyes or of muscular strain. Instruction

12. Harman, N. B.: Eyesight and Education, Trans. Ophth. Soc., United Kingdom, xxxix, 78.

in the proper use of the eyes so as to cultivate a habit. Vision of 6 18 or 6 24, with correction, is needed. Those with 6 36 to 6 60 are better placed in the blind school.

(3) *The Blind*.—This class needs the cultivation of the social sense, which they can best secure by free intercourse with the mass of the people. For this reason Harman is opposed to residential schools for the blind. In London there are ten centers for the blind. To these schools the children travel daily. They live at home with their parents and normal kindred and play with normal children. At the age of thirteen, they go for four years to two residential schools where they learn a trade.

This is the ideal; it is a happy mean between educating the blind wholly with normal children and wholly in residential schools.

Blind children above fourteen are of all grades of capacity. At present they receive their trade training all in the school. The better children are delayed in their progress by the presence of those of poorer powers, and the latter are injured by the strain of the hopeless attempt to keep pace with their betters.

Butler¹³ protests against debarring myopes of 2-3 D. from secondary schools, and asks "what right have oculists to say to the low myope that he shall not receive the best education obtainable?"

Butler doubts whether near work increases the degree of myopia. In his opinion the abolition of Gothic characters has had nothing to do with the diminution of myopia. Very high myopes with choroidal changes are more frequently found among the rural than the urban population. He points to the occurrence of high myopia—10 to 11 D.—in children two and three years old who have never looked at a book. He thinks that "until this matter of the causation of myopia has been put upon a scientific footing, there is no justification for governing a policy by it." If accommodation produces a rise of tension—as claimed by some on the basis of manometric experiments—this is a "benign" rise.

Supervision of School Children

Sym¹⁴ commends the progress that has been made in examining children's eyes in schools, but states that the work is not yet perfectly accomplished. Children are kept at tasks unsuited for them and others are forced to wear spectacles who would be better off without them. Education and civilization tend to increase the frequency of convergent strabismus and myopia. In the days

of our ancestors the myopic type could have no chance of perpetuation, whereas now it has. In a "state of nature" there is no myopia. Civilization does not produce myopia, but it suffers the myope to live and thrive. Most high myopia—15 to 25 D.—is not the result of school work and is more often found in laborers and rustics than among the literate. Sym divides myopia into three classes, as follows:

(1) Physiological: Fundus normal, no myopic crescent, vision full. In this class lenses are needless.

(2) Pathological: Vision 6 24 or less, staphyloma with wavering margin, choroidal degeneration, "speckling" about macula. Such a child will run up to 25 D. with vision reduced to counting fingers at ten feet. For such a case there is no means of prevention.

(3) Tending to become pathological: Myopia up to 3D; vision 6 12 to 6 9, narrow, ill defined crescent. He advocates mild outdoor exercise, such as golf or croquet. Full correction should be worn constantly. Sym is not inclined to correct indiscriminately hypermetropia or astigmatism in children, as low hypermetropia is apt to diminish with the growth of the eye, and there is also a change in the corneal curve tending to lessen or abolish astigmatism with the rule.

Nursery Ophthalmic Hygiene

Clark¹⁵ thinks the unilateral highly myopic eye is "abnormal" and should not be classed in any sense with ordinary errors of refraction.

Bad lighting often manufactures myopia. He has seen schools where the pupils had to face the light, so held their books close to the eyes and stooped over. A child of myopic parentage, under six, must not be taught to write; such a child should chalk on blackboard or slate at arm's length. He may also be given wooden blocks bearing the alphabet and numerals. By this "nursery ophthalmic hygiene" he hopes to prevent the onset of myopia.

Children should not sleep facing a window. Better methods of teaching, lectures, and diagrams would obviate prolonged perusal of texts and hence much unnecessary accommodative effort. "While the eye is soft, there should be more actual personal teaching and less near work and preparation from books."

Whitehead¹⁶ points out that training with blackboards cannot be continued indefinitely. What is the proper time for myopic children to resume work in ordinary classes and begin to use ordinary books? He objects to block-playing,

14. Sym, W. G.: *Eyesight and Education*, Trans. Ophth. Soc., United Kingdom, xxxix, 68.

15. Clark, E.: *Myopia and Education*, Trans. Ophth. Soc., United Kingdom, xxxix, 93.

16. Whitehead, A. L.: *Eyesight and Education*, Trans. Ophth. Soc., United Kingdom, xxxix, 39.

as stooping over them on the floor induces myopia. In many cases, myopia will cease to increase; such patients may resume work in ordinary schools. Many myopes will grow progressively worse despite all care.

"The routine in a myope school would do much to arrest the defect, and if it could be arrested up to the age of ten or eleven, the child could safely be left to go to ordinary schools."

Polock says that every child's eyes ought to be examined at least once. "Merely testing the visual acuity would not enable one to know which were the bad eyes; they must be seen and examined by one who had been especially trained in eye work."

In three myope classes during the past eight years, he had kept every myopic child under atropin, *sometimes for three years*. It was among these cases that he saw a certain diminution of myopia occurring.

Evans protests against the policy of putting myopes into the class of chronic invalids. Sudden increases in the degree of myopia come on, not after close work, but during critical periods of development or after illnesses, thus suggesting that the cause is constitutional.

Stack¹⁷ advocates early examination to catch early visual defects.

Hay¹⁸ advocates a standard of blackboard illumination in schools. In smoky cities artificial light is needed throughout many winter days. The blackboard should be *washed*, to insure adequate contrast with the chalk.

In criticism of a "leader" in a former issue of the *British Medical Journal*, Harman¹⁹ states that school myopia "is a term of currency," implying a low degree of myopia, up to three or four diopeters. There are many conditions that go to the production of myopia, whether of low or high degree—heredity, congenital defect, illness, bad social conditions, and too much close eye work. He takes issue with the writer of the "leader," who denies the influence of the last.

"School myopes," as defined above, are not admitted to the myope classes which are reserved for children who are short sighted to a serious degree, whether by reason of high myopia, scarred eyes, or congenital defect. These children are not fitted to join in the normal curriculum and the 'myope' classes were established to fulfill the need of these seriously handicapped children."

Meade²⁰ states that in progressive myopia of school children, a temporary cessation of near work, coupled with Swedish drill exercise, brings

about improvement. On resuming near work the improvement is lost and there is a tendency for the myopia to progress. This leads to the view that near work at least aggravates the condition. As varicose veins and pulmonary tuberculosis are not congenital, there being in some individuals merely a "hereditary predisposition" to these troubles, environment and subsequent life history being the exciting factors; so with myopia.

Ocular Hygiene

Morgan²¹ strongly urges an examination under cycloplegia of every child's eyes and points out that a child may have 20/20 vision and yet have a latent hyperopia up to 4D. Pain, nervous disturbances and convergent squint may appear if the refraction is uncorrected. Then, too, myopia may be prevented by early correction of astigmatism. Another advantage of cycloplegic examination would be the early detection of intra-ocular disease.

Lockhart²² gives certain rules of ocular hygiene which may be epitomized as follows: (1) work by a north light which falls over the left shoulder; (2) electric lights of high candle power hung in the ceiling and protected by frosted globes are the best artificial illuminants; (3) most people need glasses "to relieve their ocular muscles and visual brain centers of the constant and painful effort necessary to overcome the slight optical inequalities in the shape of their eyes," and not for the purpose of improving distant vision; (4) do not buy cheap tinted glasses; (5) eyes should be rested when suffering from sinusitis; (6) avoid overeating, too free indulgence in alcohol and tobacco; (7) cataract is to be avoided by general ocular hygiene.

Ophthalmology and Child Hygiene

Newcomb²³ divides ophthalmological conditions which have a direct effect on the health and development of children into the following general groups: (1) congenital defects and hereditary constitutional diseases; (2) prenatal and post-natal traumatism and infections; (3) communicable ocular diseases; (4) ocular disease arising from malnutrition and arrested development; and (5) errors of refraction and anomalies of the extra-ocular muscles. The trachoma-infected child and all suspicious cases should be debarred from school. The assumption that the eye is normal because visual acuity is high is unjustifiable. Many children with high hyperopia have good

vision and may have no symptoms directly referable to the eyes or head. The nervous system in a very high percentage of cases presents the initial symptoms of ocular strain. The more frequent nervous manifestations are nervous excitability; irritability; restlessness when asleep; dreams of an unpleasant nature; contortions of the muscles of the face or eyelids; and, as a direct result of the state of turbulence of the entire nervous system, faulty deportment in school and at home.

General improvement following correction of errors of refraction is marked with proper functioning of various organs which have no direct connection with the eyes.

Conservation of Vision

Two new pamphlets will shortly be added to the popular series on "Conservation of Vision" issued by the Committee on Conservation of Vision²⁴ of the American Medical Association: one on crossed eye and one on cataract. The Chairman of the Committee and the Secretary of the Council have held several conferences with a committee from the American Optical Association with a view to the inauguration of a campaign for the education of the public on conservation of vision and the detection and correction of errors of vision, especially among school children and industrial employees. This plan will be directed by a committee on which the Council and its Sub-Committee will be represented. Thomas discusses the inadequacy of sight for modern demands. His paper is rather discursive and touches on many topics not closely connected with the subject. Hogue²⁵ writes on "Conservation of Vision" and Wescott²⁶ on the "Care of the Eyes."

Prevention of Blindness

An editorial²⁷ in the *Boston Medical and Surgical Journal* comments on the service of National Committee for the Prevention of Blindness. In five years the Committee has grown from sixty-five charter members to 2,280 members and donors. It has sponsored and secured the enactment of laws for the conservation of vision in eighteen states.

There has been a notable reduction in the number blinded from preventable disease. In forty-four schools and day classes for the blind, 105 of 622 new admissions were due to blindness from ophthalmia neonatorum. The percentage for this disease is 16.9, an increase over last year's re-

port of 2.2 per cent, but a marked decrease over five years ago. Blindness due to wood alcohol has increased greatly. Trachoma is under better control. Eye accidents are fewer. Follow-up work by special social service nurses in cases of eye troubles has proved to be of considerable value, inasmuch as many people, through ignorance or carelessness, neglect instructions or fail to keep in touch regularly with hospital clinics, and in consequence suffer deterioration or destruction of vision.

By means of stories, talks, slides, and moving pictures, the young people are being brought to a realization of what good vision means.

To conserve the vision of the rising generation, every child's eyes should be examined by an eye specialist on entering school, and once a year thereafter.

An editorial²⁸ in the *Journal of the Missouri State Medical Association* states that trachoma is increasing in Missouri and constitutes a very real danger.

Woodruff²⁹ discusses the creation of the Missouri Commission for the Blind, pensioning the helpless blind, ophthalmia neonatorum, etc.

Harris³⁰ notes the sudden increase in blindness from wood alcohol and agrees with Berry, who urges special legislation to prosecute and punish those who substitute this poison for alcoholic stimulants. Educational work is best carried on by lectures and press articles. Recently a staff of oculists has been appointed by the Missouri Commission for the Blind.

Black³¹ gives a systematic review of the work for prevention and treatment of trachoma, and the military orders relative to the induction or rejection of registrants with trachoma. He also reviews the management of the trachomatous in Chinese and Egyptian labour companies abroad.

Climate and Ocular Disease

Santos-Fernandez³² states that a warm climate tends to diminish the number and seriousness of many ocular troubles, as hygienic rules can usually be followed with more ease.

In the public schools the illumination of the class rooms does not need to be increased; on the contrary, it is necessary to devise means to reduce the glare from the brilliant sunlight.

Retinal hyperesthesia with consequent asthenopia is common, due to the bright sunlight, especially among workers at the sea shore, sponge fisheries, and fishermen.

THE FUTURE OF MEDICAL PRACTICE

COMMENT was made in the January issue of MODERN MEDICINE on the address of the late Prof. William T. Sedgwick delivered at the centennial celebration of the Medical College of the University of Cincinnati, this address having later been published as the leading article of *Public Health Reports*, January 28, 1921. The contribution merits additional comment, however, pointing as it does to new departures in medical practice, in what may reasonably be considered as adequate preparation for the members of the medical profession, and defining the line of cleavage between what constitutes clinical medicine and the field of public health.

The inadequacy of medical service generally and the fact that the best type of service is not available to the masses involve no invidious criticism of the practising physician, for it may safely be conceded that the ethics of the medical profession is of high standard and that it is as uniformly operative as can reasonably be demanded of any single group of men. The scientific training, mental habit, and the definite limitation of interest in the medical profession conduce to highly specialized activities and promote notably high objectives.

In such concentration of interest, however, there do arise the dangers of over-specialization and it becomes a problem to maintain in such specialized workers that degree of sustained interest in the less spectacular phases of medicine which will insure safety for all the people from all preventable maladies. High mortality rates are to be attributed, not to the rare and interesting diseases, but to the everyday practices of the people, to faulty food habits, to undue and prolonged fatigue, to improper working conditions, and to the more common infections that are easily guarded against, but which on the whole offer no absorbing interest to the scientific worker. Their

care and cure require wholesale measures of vigilance combined with the drudgery on the part of the physician in honest, even though it may be dull, routine work.

A case in point may be mentioned in a promising young physician of our acquaintance who is now doing post-graduate work, at the conclusion of which he purposes to seek another field. His present work is pressing and remunerative, but he feels the urge to find a niche where there are newer features and less routine, the tendency everywhere being for the younger and more progressive professional men to keep in close touch with the great centers of research. Undoubtedly out of such situations have developed the "group" idea, which frees a man from routine and permits him to follow the lines of his special interests. It relegates to the social or psychiatric worker the task of filling in the gaps, and under good organizations effects a well rounded service. Let us not deceive ourselves into thinking that altruistic motives, social consciousness or anything other than the dynamic energy of individual interest in his work will serve to keep the physician or anyone else consistently at an arduous task. One phase of the problem, then, is the manifest necessity of devising some means of bringing the isolated physician and general practitioner into essential and continuous contact with the profession as a whole.

The real remedy, however, would seem to lie in the direction indicated by Professor Sedgwick in a system of education that would provide a line of cleavage as soon as the fundamentals of medicine are acquired whereby, on the one hand, the school would produce our surgeons and internists and, on the other, the needed human engineers. Men are needed everywhere for public health work who can bring to their office the scientific training plus epidemiology, sociology, psychiatry, a knowledge of vital statistics, and a faculty for organization. Some

source must be provided for the training of large numbers of such workers if this important domain of medicine is not to be usurped by a mere police power or by the sanitary engineer.

The procedure proposed by Professor Sedgwick would provide the sort of background for an interest in the wider aspects of human welfare which would put public health work on the high ethical basis of an exact science, and the initiative of the individual medical practitioner would in no way be jeopardized. Some such compromise between individual and social needs must be effected. Nations rise and fall on the manner in which such adjustments are made.

S. P. M.

SURGICAL TREATMENT OF PERNICIOUS ANEMIA

RECENT contributions on the surgical treatment of pernicious anemia show an interesting concurrence of opinions. The conclusions reached by the great majority of authors are as follows: Towards the cure of pernicious anemia surgery offers no more than medicine. As far as the alleviation of symptoms is concerned, it is generally agreed that transfusion may hasten a remission. Splenectomy is of doubtful value.

These conclusions have been reached after much work and many trials. Blood transfusion had been enthusiastically advanced by many as a powerful weapon against pernicious anemia. By some, at first, it was vaunted as a cure. Later, when it was found that the early claims were not substantiated, many were willing to put this procedure into the discard. Splenectomy, too, when first proposed, was looked upon as a possible cure, but at present most writers feel that the results do not justify the operative risk.

Bloomfield¹ claims that blood transfusion performed at a time when the patient was not refractory brought on a remission in about one-half the cases. Following transfusion, the number of red cells and the hemoglobin could be brought to a higher level than in the untransfused cases. He compares the results in cases treated medically, that is with rest, diet, arsenic, etc., with those treated surgically. He answers the question whether or not transfusion can help tide over a severe relapse with the following figures: Of 363 patients treated in the Johns Hopkins Hospital, 16 per cent died in the hospital; of 31 patients who were transfused, 19 per cent died; of 332 not transfused, 15.5 per cent died in the hospital. He records a series of 57 cases; of 26 transfused patients, 23 per cent died; of the 31 not transfused, 23 per cent died. In other words, it would appear that blood transfusion does not tend to reduce mortality. Bloomfield is dubious regarding the value of splenectomy. Blood transfusions are not "held" better following splenectomy. Central nervous system symptoms are benefited neither by splenectomy nor transfusion. He quotes Ottenberg and Libman as saying that transfusion leads to remission in about half of the cases.

Anders² concurs with Kimpton that transfusion offers more than any other form of treatment and that the results of splenectomy, either with or without transfusion, are no better than those obtained by transfusion alone. He does not believe that the operation of splenectomy is warranted by the results. Anders believes in early transfusions, a conclusion reached after a study of 450 cases reported in recent literature. He claims that transfusions initiate prompt remissions in 56 per cent of

cases. He quotes Weber³ and Hurter⁴ as advocating repeated small transfusions.

Lindeman⁵ states that one of the main factors in producing the symptoms in pernicious anemia is the very low blood volume, and he prefers large transfusions.

Graham⁶ and Schaff⁷ claim that blood transfusion in pernicious anemia has a beneficial action but no curative value. Carr⁸ agrees that transfusion does help, but reminds the reader that accidents occasionally occur during or after the procedure.

Griffin, H. Z., and Szlapka⁹ have recorded statistics of 50 cases of splenectomy for pernicious anemia, operated upon more than three years ago. They feel that splenectomy has prolonged life in at least 20 per cent of the cases. The operative mortality was 6 per cent—that is, 6 per cent of the 50 cases died in the hospital; 21.3 per cent of those who recovered from the operation lived three years or longer; 10.6 per cent are still alive, more than than four and one-fourth years after operation. There is no way of telling prior to operation, from the condition of the patient, his previous history, etc., whether or not he will respond favorably to splenectomy; however, the type of case in which there is evidence of active hemolysis seems to show most marked immediate improvement. These authors feel that splenectomy acts rather favorably than otherwise in cases with central nervous system symptoms. Of the five cases living more than three years after splenectomy, two cases had relapses and transfusions, the others stayed well. In Griffin and Szlapka's cases splenectomy was constantly followed by an immediate remission. Regarding foci of infection, they say, "while we still advise the removal of septic foci, believing that they may well have a physiologic and possibly an etiologic relation to pernicious anemia, we have been gradually forced to some doubt as to their grave importance in the stage of pernicious anemia in which our patients present themselves for examination."

Sir Berkley Moynihan,¹⁰ in a recent article entitled the "Surgery of the Spleen," read before the Royal College of Surgeons, under the subheading of pernicious anemia, presents the statistics from the Mayo Clinic, as quoted above, but is rather non-committal concerning the value of splenectomy. He writes, "In the first place, it cannot be claimed, and is not claimed, that any patient has been cured of his disease. The risks run in undergoing the operation are small, but not so insignificant that they can be ignored. A few lives are sacrificed. All the patients who survive are not benefited, but in the majority a degree of improvement results and a prolongation of life in greater comfort, with increased zest, can be recorded." In the conclusion of the article, referring to those diseases of the hemopoietic system associated especially by clinicians with predominating splenic pathology, he states, "Instead of searching only for the existence of this or that splenic disease, an inquiry should be directed to the determination of the functional capacity of all the various organs likely to be deranged. . . . It may be that splenectomy in any of those diseases will remove the obvious culmination of the morbid process and thus bring about 'a cure' of the disease or an arrest of its development;

but it does not by any means follow that all the other related parts are thereby caused to return to their normal state."

Da Costa¹¹ states that primary pernicious anemia is probably due to a toxin which is intensified by splenic

action, hence splenectomy may be done. It produces at least great temporary improvement.

Ranzi,¹² writing from von Eiselsberg clinic, claims that splenectomy is not a cure for pernicious anemia.

R. B. B.

THE ETIOLOGY OF HYPERTRICHOSIS—A REVIEW OF THE LITERATURE

BY PAUL S. LOWENSTEIN, M.D., St. Louis, Mo.

A VERY casual reading of the literature on hypertrichosis for the past ten years reveals a striking variety of opinions and beliefs concerning its etiologic factors. It was with the object of summarizing these apparent discrepancies that this review was undertaken.

Freshwater²³ defines the condition as "an increase of hair, as regards either region, degree, age or sex." He distinguishes two general types (a) congenital and (b) acquired. It is not the intention of this paper to treat of the former, which includes such conditions as hairy moles, the hairiness accompanying spina bifida, etc.

Factors in Causation

According to McEwen,⁶⁷ practically all cases of hypertrichosis have in their causation one or more of the following factors.

(1) Heredity he cites as the most frequent cause, and quotes certain racial tendencies and the fact that it is often found among members of the same family. That heredity bears an important part is also emphasized by Freshwater, while Weber⁹¹ stresses the "Simian type" as an example of "degenerative" reversion.

(2) Ill chosen treatment, although of secondary significance, often becomes a very important factor in severe types, due largely to the commercial beauty parlor.

(3) The condition may be due to antecedent inflammatory dermatoses, such as are often seen following prolonged and severe acne, particularly facial. In this group, according to Freshwater, may well be placed those cases occurring after prolonged applications of irritants, such as sinapisms.

(4) A group not emphasized by McEwen is the incidence among mental defectives and insane patients noted by Bainbridge¹ and Freshwater, although Ewart²⁶ points out that in this latter class certain other factors—the endocrine glands—are primary in the causation of increased hair growth.

(5) By far the greatest amount of interest has been focused on those cases ascribed to disturbances of function of certain of the endocrinous glands. McEwen⁶⁷ adds: "The glands which have been proved experimentally to be related to the pilary system are the thyroid, hypophysis, the suprarenals, and the gonads;" but the literature also contains many references to the pineal, thymus, and parathyroid glands, which factors will now be reviewed seriatim.

Thyroid Exerts an Influence

According to Root,⁷⁶ "the only diseases which can, with assurance, be attributed to an absence of or derangement of function with the ductless glands, are those referable to the thyroid."

That this gland has a limited but definite effect on the hair is emphasized by Leopold-Levi:⁷⁵ "Slight symptoms

of hyperthyroidism . . . constitute the prevailing characteristics of Grave's disease," among which he includes "hypertrichosis, more particularly of the eyebrow," and this sign is also quoted by Stewart.⁸³ McEwen⁶⁷ inclines to Leopold-Levi's theory, that "the thyroid has an essential action on the hair growth of the scalp, the eyebrows, and the eyelashes." So, too, hypertrichosis is mentioned among the symptoms of slight hyperthyroidism, as given by Reuben,⁷⁵ while Granger¹³ comments on the fact that in pregnancy, where a physiologic thyroid enlargement occurs, the hair may become fuller and thicker.

Conversely, in thyroid deficiency, Cobb¹⁷ believes that the "eyebrow sign" is of considerable diagnostic significance. There is a sparseness of the outer third of each eyebrow with a scarceness and partial falling out of the whole eyebrow." That hirsute derangements are important in the diagnosis of hypothyroidism is asserted by Ewart,²⁶ Falta,²⁸ Hertoghe,¹⁶ Leopold-Levi,⁷⁵ MacLeod,⁷⁹ Reuben,⁷⁵ and others.

It has been shown experimentally by Paton⁷² that in animals after thyroidectomy, there is a decreased growth of hair, particularly in the younger individuals, although it has not been proved whether this is due to the loss of a specific thyroid effect on hair growth, or whether it involves merely a lowered general metabolism. Of much practical value is the demonstration that in hypothyroid conditions thyroid medication causes a growth of hair, as in the cases cited by Hertoghe,¹⁶ MacLeod⁷⁹ and Sharp.⁷⁸

However, there seems to be some variance of opinion regarding the result of thyroid states on pilary growth, for Gordinier⁴² and Soble⁸¹ claim that in hyperthyroidism hirsuties is absent, while Stewart,⁸³ quoting Walsh, states that in many cases of exophthalmic goiter there is "a band of alopecia at the frontal end of the scalp."

This gland has been studied by observations after experimental and therapeutic partial or total removal, by clinical data on presumed cases of diminished or increased secretion, and by the administration of the gland either *in toto* or of one of its lobes.

That the hypophysis is very much concerned with the growth of hair is the opinion of Bandler,⁶ who believes furthermore that the anterior lobe "is more a male than a female gland, and the posterior lobe is more a female than a male gland." Cushing²⁹ is more conservative in his statements, concluding that inasmuch as hypertrichosis has also been described in connection with lesions of other glands, "it is impossible to speak with any degree of assurance of this or that gland as primarily at fault;" while MacLeod,⁷⁹ too, is uncertain as to the relation of the pituitary gland to the skin. That the pituitary undoubtedly functions early in life has been proved experimentally by McCord,⁶¹ who found the active principle in eight month fetuses.

Cushing¹⁹ and Crowe, Cushing, and Homans¹⁸ found that

after partial removal of the anterior lobe in puppies, hypotrichosis supervened, together with persistence of infantilism, and these results were confirmed by Aschner,² and Benedict and Homans.¹²

The syndrome known as *dystrophia adiposo genitalis*, first accurately described by Fröhlich,³⁴ is accompanied by a hypotrichosis. Climenko and Strauss³⁶ conclude that the eunuchoid is "a product of deficiency in the adjustment" of the endocrine glands, but note that the pituitary is often involved.

Stephenson³² reported a case on whom he made the diagnosis of "dyspituitarism," in a sixteen year old girl, with bilateral simple optic atrophy, temporal hemianopia, x-ray evidence of enlargement of the sella turcica, and no pubic hair; while Falta²⁸ noted the disappearance of the pubic and axillary hair in hypophyseal tumor and ascribed the cause to hypofunction of the hypophysis, pointing out that removal of enough of the tumor to relieve pressure on the still healthy part of the gland caused the axillary hair to grow again, as in two cases reported by von Eiselberg. This is in accord with the findings of Cushing and Goetsch³¹ that retrogressive changes on the part of the secondary sex characters occur if the hypopituitarism affects adults, and Reuben³⁵ attributes this to a deficiency of the posterior lobe.

Contrary to these observations are the views expressed in cases reported by Jona³⁰ and Moleen,³⁸ in which the occurrence of hypertrichosis was ascribed by them to a pituitary insufficiency, while Cobb¹⁷ and Falta²⁹ state that in *Dystrophia adiposo genitalis* there is frequently an abundant development of the hair on the head, and the latter author often observed in these eunuchoids lanugo hairs on the face, particularly in front of the ears and on the skin and upper lip, but no mustache or beard, little or no axillary hair, and but few on the mons veneris.

The experiences of Harrower⁴⁴ and Reuben³⁵ agree with that of Cushing,³⁰ who described many instances of hypertrichosis accompanying hyperpituitarism, while Goetsch³⁰ modifies this by limiting the cases to those in which the hypophyseal overactivity antedates normal adolescence.

Many writers concur that hypertrichosis frequently ensues in acromegaly (Cobb,¹⁷ MacLeod³⁹), particularly in earlier stages or in exacerbations of the disease, according to Walker,⁴⁰ but Paton⁷² quotes Marie's investigations as demonstrating that many giants have a poor growth of hair. The association is thus expressed by Falta:²⁹ "In many cases of acromegaly, there occurs both in men and women abnormally abundant hairiness. In women the hairiness may assume quite the masculine type. The growth of hair on the head is often remarkably dense and the individual hairs are thick. In the course of the disease abnormal hair growth occurs on the trunk and extremities. Often too, the eyebrows become bushy."

Results of Pituitary Feeding

The most interesting pituitary feeding experiments have been performed by Goetsch,³⁸ who found that rats fed with anterior lobe developed coarser, thicker hair than controls. The posterior lobe had no such effect, and he concludes that the anterior lobe "has a stimulating effect upon the growth of the animal and upon the sexual development and activity. Posterior lobe extract, when thus given, has a retarding influence." Haynes⁴⁵ reported a case of a girl to whom the *pars intermedia* was administered, followed by normal development, growth of pubic hair, etc., but this may simply have been due to the usual onset of puberty.

The literature of recent years is replete with references to the relation of the suprarenal cortex to hair growth and the belief is apparently gaining that this gland is of great importance in the causation of hypertrichosis, either by direct stimulation or by a secondary action on other endocrine organs.

Falta²⁹ believes that very probably the heterosexual hairiness of women can be referred to a hyperfunction of the adrenal cortex, and suggests that there is the same cause for the virile type of hairiness observed in acromegalic women or even in normal women during pregnancy, inasmuch as hyperplasia of the adrenal cortex is observed in both conditions. He states, furthermore, that the cortex exerts "an important trophic influence on a very important sexual character, namely the hairiness," and quotes Glynn as corroborating this opinion. Vincent,³⁸ too, concurs in this observation, but calls attention to the fact that most of the evidence is of a clinical nature. He disagrees with Halban's explanation that the "*Hypertrichosis gravidatis*" may be ascribed to a protective action of the placenta, and explains the tendency of any facial or body hair in the pregnant woman to increase in amount, as due to enlargement of the adrenals.

While assenting to the views expressed by Falta and Vincent, MacLeod³⁹ has also noted the converse—that in connection with defective adrenals there is a disappearance of the pubic hair and non-development of the genital organs.

Apert¹ has given the name "Hirsutism" to a symptom complex associated with hypertrophy or tumor of the adrenals and this classification has also been adopted by Barker.⁷ They divide the cases into three types depending on the development of the patient when the hyperfunction occurs: (a) Embryonal period: here the condition of pseudo-hermaphroditism is prone to develop.

(b) Childhood. The child matures too soon (*pubertas praecox*), with growth of pubic and axillary hair, menses, and adolescent psyche. (c) Period of sex constancy. The body may become slowly or quickly covered with abundant growth of hair (hirsutism), and in the female there may also occur the growth of a beard, large clitoris, deep voice, and other characters of virilism.

Apert claims that in all these cases adrenal tumors develop, although their site may be elsewhere in the abdomen in such locations as the kidney, ovary, testis, accessory adrenals; but Herzog⁴⁸ did not find tumors in all of his cases.

Bell⁴¹ has made the important observation that there is no record of a suprarenal lesion producing changes in the secondary sexual characters in a woman after the menopause, although frequently "after this period of life the characteristics may normally incline towards the masculine type." He explains this latter anomaly "by the fact that sex, as such, has ceased to exist and that, although the withdrawal of certain feminine functions and characteristics may lead to the latent masculinity developing to a slight extent, no further sex demonstration can be aroused, even though the masculine-producing organs be disturbed."

Gallais⁵⁵ insists that in suprarenal tumors, particularly hypernephromas, the progressive development of hypertrichosis of the masculine type in young individuals is absolutely constant, to which Lucien and Parisot⁵⁷ in general agree, although they ascribe some cases to adrenal hypertrophy. Jump, Beates, and Babcock⁵¹ are emphatic in their conclusion that in a given case, particularly if a girl in whom there is development of the male characters and a lessening of the female characters, "there is presump-

tive evidence that there is a hypernephroma of the adrenal cortex."

Adrenal Hyperplasia and Sex Characters

A somewhat more conservative attitude is assumed by Glynn,³⁷ who finds that in females adrenal hyperplasia is associated with diminution of female characters and with the development of male characters, and that premature development of sex characters in the male may be associated with tumors of the cortex.

According to Strauch,³⁴ adrenal tumors effect "merely a hastening influence on the development of the secondary sexual characteristics, causing also an excessive growth of the body," and these tumors are five times more frequent in the female than in the male. McCord³⁴ has shown that the active principle of the gland may make its presence felt very early, having been found in six month fetuses. Ewart²⁶ has stressed the frequency with which insane patients, particularly in adolescent life, develop hypertrichosis, and he expresses the belief that the adrenals are an important factor in its causation.

There are numerous cases in the literature of precocious sexual development associated with suprarenal tumor. Jump, Beates, and Babcock³¹ in publishing a case, review seventeen previously reported cases in children, of whom fourteen were girls and four boys. There was overgrowth of pubic hair in all, facial hair in fourteen, and axillary hair in five. Of the eighteen cases all died before they were sixteen years old. In twenty-one cases of sexual precocity, Neurath⁷⁰ found adrenal neoplasms in ten or eleven. Bulloch and Sequeira¹⁵ reported tumors of the adrenals in ten patients, of whom two were boys and eight were girls. Tuffier,⁵⁶ in reviewing hypertrichosis in infants, finds the signs are of remarkable constancy, with hairiness of the masculine type as the most common symptom, occurring in thirty out of thirty-two cases. He reports a number of instances, and more have been described by Askanazy,³ Baldwin,⁵ Cobb,¹⁷ Elliott,²³ Thumin,⁵² and others.

The frequency with which pseudohermaphroditism, particularly of the female type, is associated with hyperplasia of the adrenal gland or accessory adrenals, is suggested by Vincent³³ as "illustrating the tendency of the gland to be associated with the appearance of male characters in the female." Herzog¹⁸ found adrenal hypertrophy in thirteen cases of pseudohermaphroditism and similar instances have been reported by Fibiger³¹ and by Quinby.⁷⁴ In a well-written article, McAuliffe⁷² expresses the belief that the fundamental cause leading to these marked variations in sex characteristics is a disturbed pluriglandular equilibrium, but assumes that the suprarenal is the gland principally concerned, then the pineal gland, hypophysis ovary, thymus, and thyroid, in order of their importance.

Gonads and Secondary Sex Characters

That the gonads are intimately associated with the secondary sex characters has been recognized for centuries in those countries where castration of the human male, and of various domestic animals, has been practised, but following the experimental work of recent years, the relation has assumed a new interest and importance. Although much light has been shed upon some of the processes involved, that many divergent opinions exist may be judged from the following assertions.

The view of Vincent³⁷ that "secondary male characters are normally present in a latent form in the female, and the ovaries exert an inhibitory influence over their development," has been maintained by Paton,⁷² Goldschmidt,⁶⁰ Goodale,⁴¹ and others. This has been demonstrated very clearly in an interesting article by Goldschmidt, who

points out the fact that castration of the female birds causes the assumption of the characters of the male sex, and also that the old female birds often assume the cock feathering. Corroboration of these conclusions is furnished by some pheasant breeding experiments of Smith and Thomas,⁸⁰ who found that ovarian degeneration is accompanied in every case by the assumption of some degree of male plumage, and to a marked extent in most cases. They believe that they "are warranted in concluding that there is an organic correlation between plumage and ovary," and that to have normal female plumage a normally functioning ovary is necessary.

In a comprehensive monograph by Goodale,⁴¹ reviewed by Morgan,⁶⁹ the conclusion is reached that there is a specific relation between the gonads and the secondary sex characters, and a very close adjustment of the secretion of the ovaries to the characters it modifies, inasmuch as male characters produced in a given female are like those of the corresponding male. The author contends that this secretion must be relatively simple, for, if it were of complex nature, one substance producing each effect involved, such close coordination as actually obtains could hardly be anticipated.

For the production of secondary characters of the opposite sex it is not merely sufficient that the ovaries be absent, according to Bond,¹⁴ but the presence of male sex gland elements—the stimulating factor—is essential, and, conversely as stated above, full male characters may be assumed to be inherited by both sexes, but in the female these characters are normally held in check by an ovarian secretion (Goodale,⁴¹ Loeb,⁵⁶ Paton⁷²). Much weight is given these views by the observation of Vincent³⁷ that following castration of the male there is never reversion to a type resembling the female, Dutoit²⁴ even mentioning hypertrichosis sometimes occurring after castration; on the other hand Kerwin⁷² maintains that such male features as facial hair, or change in voice, never occur after oöphorectomy, but that "such ideas have been acquired by reasoning from a reversed analogy to eunuchs." Ewart²⁶ further points out that the secretions or lack of secretions of the ovary cannot alone be responsible for hypertrichosis, for there are comparatively few women who develop a hairy overgrowth at the menopause. Quite in line with these assumptions are the observations by Goetsch³⁸ in feeding rats with ovarian extract, that corpus luteum "has a stimulating influence upon the female, and a retarding influence upon the male sexual development."

Effects of Hormones

La Mer²⁴ is very enthusiastic over the work of Tandler and Kellar, and of Lillie, on the freemartin, in which, owing to an anastomosis of blood vessels, the female fetus receives the hormones of the male fetus. The effects on the female vary according to the period of fetal life at which this juncture occurs: (1) if late in fetal life, male secondary sex characters are displayed, and sterile ovaries are produced; (2) if earlier, testicular tissue actually is found in the ovaries; and (3) the author presumes that in anastomoses occurring prior to ovarian differentiation, there may be a complete sex reversal. However, Goldschmidt⁶⁰ views these factors from a different angle, contending that the determinants of sex characters are distributed by means of the chromosomes.

Blanchard¹⁹ takes decided exception to the beliefs of Apert,¹ Gallais,³⁵ Tuffier,⁵⁶ and others who claim that the cause of hirsutism and virilism is due to lesions of the adrenal, and cites examples of virilism in many birds and mammals, furthermore stating that the ovary is the only

cause for this inversion of sexual characters in the female, as is the testis in the male. He concludes that a lesion or atrophy of the ovary is the cause of virilism, and his point of view is shared by Marie,⁶⁰ who considers that virility or femininity is always due to modification of function of the genital glands. It is essentially the attitude of Herzog¹⁵ that sexual precocity is due either to an increased irritability or to a cessation of inhibition of the gonads; and Shoemaker,¹⁹ while conceding the influence of the hypophysis, pineal, and adrenals, upon the testis, asserts that the internal secretion of the gonad is responsible for hair growth.

The foregoing summarizes the prevalent views assuming changes in the secondary sex characters as originating in the gonads or, as Herzog states it "hypergenitalism;" but some investigators claim other causative factors. Thus Exner²⁷ believes increased activity of the anterior lobe of the pituitary either inhibits this function or directly causes such changes as increased amount of hair, and Barker⁸ suggests that, while hyperactivity of the gonads exists in cases of *pubertas praecox*, pathological processes in other endocrine glands—pineal, adrenal cortex, etc.—seem to be the stimulating factor. However to Frank³² it is clear, that in the female "no matter what the origin of the stimulation or depression may be, the symptoms produced are identical with symptoms arising from primary stimulation or depression of ovarian function"; and Bandler,⁶ too, finds that the testis is responsible for the characteristic male qualities, both by its own action and by its stimulation of the adrenals, pineal, and hypophysis.

McEwen⁶⁷ quotes Leopold-Levi as affirming that "the ovaries and testicles have an essential action on the hair growth of the pubic and axillary regions. The testicles, in addition, have a direct action on the hair of the body, the beard, and the upper lip. The hypophysis and adrenals indirectly through the testicles influence the body hair, exclusive of the scalp region, the eyebrows, and the eyelashes." There is general accord that the rôle of the gonads in the causation of secondary sex characters is due to the interstitial, lipin-rich cells of the testis, and to the interstitial or oögenic cells of the ovary (Bandler,⁶ Blanchard,¹³ Marine,⁶¹ and Paton⁷²).

Numerous instances of the relation of the sex glands to secondary characteristics have been reported in the literature. In twenty cases of hypertrichosis coming to operation or autopsy, Neurath⁷⁰ found five who presented neoplasms of the sexual organs. Flata³⁶ describes a number of cases associated with tumors of the testes or ovaries. After removal of the tumor the hypertrichosis either retrogressed or disappeared. The patient of Sacchi, as quoted by Herzog¹⁵ and Paton⁷² is a typical example: A boy of nine and one-half had displayed for four years an enormous growth of bones, great muscular development, deep voice, long beard, and pubic hair. An alveolar carcinoma was removed from his left testis, and subsequently his secondary sex characteristics became those of a normal boy of his age. Other interesting material has been presented by Cobb,¹⁷ Herzog,¹⁷ Machell,¹⁸ Sailer,¹⁷ Shoemaker,¹⁹ and others.

Pineal Tumors and Hair Growth

Many authors have found in young subjects with pineal tumors unusual hair growth and premature sexual and genital development. The presumption is, according to Vincent,⁶⁵ that these changes are due to pineal hypofunction, the pathogenesis depending upon a destructive lesion or growth of the pineal body. Foa found marked development of the testes and secondary sex characters in pineal-ectomized cocks, and Herzog¹⁵ therefore concludes that the

pineal gland inhibits the development of the testes and directly or indirectly the development of secondary sex characters, at least in males. Dercum⁷³ is one of the writers who also incline to this opinion, while Reuben⁷⁵ believes that pineal enlargement cause increased genital hair and general body hirsuties, and this latter view finds some substantiation in the feeding experiments of McCord,⁶⁵ in which by administering pineal substance by mouth or by injection into animals, precocity of development was obtained.

However, these views have been warmly assailed by numerous investigators, such as Dandy,²² who after removing the pineal of animals, "observed no sexual precocity or indolence, no adiposity or emaciation, no somatic or mental precocity or retardation." He maintains that the pineal has no important, active endocrine function, and is not essential to life or well being; and Park⁷¹ in reviewing an extensive bibliography, arrives at the same conclusions. These important observations are strengthened by Fenger's³⁰ report of the examination of eight thousand pineal glands of cattle, sheep, and lambs, in which he discovered no evidence warranting the acceptance of a pineal function.

After considering the seventy cases of pineal tumors reported to 1918 and finding the large majority without sexual precocity or abnormalities of the genital organs, Root⁷⁶ decides these changes cannot be ascribed to a functional pineal derangement, and H. H. Bell¹⁰ has discovered no functional disturbances in other organs in association with pineal hyperplasia. McCord⁶⁵ ventures that many cases of unusual development in patients with pineal tumors may be due to a pluriglandular involvement, and W. B. Bell¹¹ remarks that, while one might anticipate the development of masculine characteristics in adult women with pineal tumors, no such cases are on record; for, as Strauch⁷⁴ observes, it is only in male precocious children that pineal tumors are found.

McCord⁶⁵ quotes Cushing as indicating that the functions of the hypophysis are readily deflected from the normal by intracranial changes accompanying pineal neoplasms, and in a case of sexual precocity and hypertrichosis, reported by Horrax,⁴⁹ a pineal tumor was found at autopsy to have invaded the pituitary. Those cases of pineal tumor in which sexual precocity occurred were chiefly teratomas, as in Biedl's case reported by Herzog.⁴⁸ H. H. Bell¹⁰ reported two cases of pineal hyperplasia without obvious metabolic disturbances, and Neurath⁷⁰ in compiling twenty cases of sexual precocity seen at operation or at the autopsy table, found pineal neoplasms in three.

The Thymus Gland

The relation of this gland to hair growth has been reasoned largely by reverse analogy, for it has been shown by Klose and Vogt³ that following thymectomy in young pups the hair becomes rough and falls out. The contrary is stated by Paton,⁷² presenting instances of thymic hyperplasia with lack of hair growth and infantile development of the reproductive organs; and MacLeod⁷⁹ suggests that the secretion of the thymus "inhibits sexual development with its associated hair growth."

The Parathyroids

There is a very scanty literature on the subject. Pfeiffer and Mayer⁷³ noted a great shedding of the hair in rats during experimental tetany, their theory being that removal of the parathyroids leaves a poison in the blood. Paton⁷² produced chronic tetany in animals by gradually ligating the blood supply to the parathyroids, and the hair whitened and fell out.

In summarizing these numerous deductions, the words of Gley²⁸ seem very apropos: "Without a physiological study of the organs of internal secretion, hypotheses are being too liberally formulated. The theory of reciprocal relations is insufficiently demonstrated."

MADAM CURIE VISITS AMERICA

On the occasion of her visit to the United States in May. Mme. Marie Curie will be presented with a gram of radium, the precious metal of which she is the discoverer, as a gift from prominent American women. Dr. F. C. Wood of the Crocker Memorial Cancer Research Laboratory heads a committee of scientists who will receive the distinguished French woman. Facilities have been arranged for her to demonstrate and experiment in American laboratories.

in Poland. Just as the fight for civilization was not on our own shores, so do boundaries break when disease threatens. The cause of Poland is the cause of all humanity, and if typhus is to be checked in its menace to the whole world, it must be wiped out in the original foci of infection. The physicians on the mission are headed by Dr. S. N. Schmidt. From left to right, they are: Front row.—Drs. Jack Alcazar, S. M. Schmidt, head of the delegation, Samuel Neuman, S. Fleisig, M. J. Colton, Irwin Michlin, Samuel Lovish, and Reuben Friesman. Back

row.—Drs. Louis Silver, Samuel Flx., M. M. Anshin, Z. Sayet, R. Kohn, S. Wendkos, H. Apfel, Joseph Golub, and Z. A. Bonoff.

DR. BRAISTED GOES TO PANAMA

THE establishment in Panama of an institute for the study of tropical medicine is a fitting memorial to the late Major General William C. Gorgas. Dr. William

Central News Photo Service
DR. WILLIAM C. BRAISTED

C. Braisted, president of the American Medical Association, who has been chosen as chairman of the committee which is making arrangements for the project, has just sailed for Panama to assume the responsibilities of this office.

The purpose of the Institute will be to promote biological research in fauna, flora, geology, soils and climate, with due reference to medicine, agriculture, forestry and fisheries, and, in general, all scientific objects that will promote the development of the American tropics.

Institutions which have already expressed their intention to participate actively in the work include the Smithsonian Institution of Washington, D. C.; the Museum of Natural History, American Geographical Society, New York Zoological Society, and Brooklyn Botanical Garden of New York; Academy of Natural Sciences and the Commercial Museum of Philadelphia; Field Columbian Museum of Chicago; Carnegie Museum of Pittsburgh; Harvard and Yale universities, Johns Hopkins University, universities of Pennsylvania and Michigan, and the National Geographic Society.

The plan for organizing the Institute originated with the Division of Biology and Agriculture of the National Research Council. A temporary Executive Committee is now working on the proposed constitution and by-laws.

HEALTH WORKERS TO THE FRONT

Whatever the emergency, the value of public interest in health conservation and the advantage of volunteer health workers may be relied upon in making immediately effective the measures of preventive health work. Here is pictured a group of workers fighting the spread of small-

pox in East Chicago, Ind. The workers and their male helpers are preparing gauze for use in smallpox cases. From left to right they are Lillian Young, Municipal Judge H. M. Cohen, Carla Pearson, Gertrude McLaughlin, Mrs. Ray Stephenson, and E. N. Sawyer.

STUDIES IN INFANT PARALYSIS IN VERMONT

The increase in poliomyelitis this season is in accordance with the curves of the disease established by the State Health Department of Vermont, by which a rise in the figure for 1920 is quite plainly forecast.

In discussing the geographical distribution in Vermont, Dr. W. L. Aycock says: "We know now that the disease spreads from person to person; that an individual suffering from the disease may harbor the virus in his nasal passages, and may infect others; furthermore, that a healthy person may transmit the virus without having the disease; that the disease is not limited to children; that it occurs in an abortive form—that is, without paralysis—and that unrecognized abortive cases may play a large part in the dissemination of the virus." Certain facts are adduced by Dr. Aycock to show that one year's cases result from previous ones, with occasionally a reinforcement from the outside.

WORK HERE AND LIVE LONGER

HERETOFORE collective health has not been made the objective of the group. It has been an attribute generally held in the same category as other vague ideals—good to contemplate, but regarded as impractical and unattainable. Suppose this mental attitude toward medical supervision in a given industrial plant were changed from the usual apathy into an aggressive campaign for the proper type of medical supervision supported by cooperative effort on the part of both employer and employed to eradicate all unnecessary accidents, to lengthen the life of the average employee by means of improved working conditions, and to reduce illness to the least possible minimum—the campaign having for the slogan of the plant “Work here and live longer.”

What would it mean to the average employer to be able to prove the death rate in his plant to average 10 per cent lower than other similarly employed groups? How marked would be such an advantage in terms of increased production? How much would the unit cost of reduction be lowered if every man in the plant were healthy in mind and body? What would be the effect on relations and turnover?

That this ideal is approached in some plants is evident from the published records. Fluctuations in illness as affecting workmen bear a direct relation to industrial medical service. The data being compiled under the supervision of Mr. Brundage, assistant statistician of the United States Public Health Service, show fluctuating rates from plant to plant which are most significant. On closer analysis many of these differences will disclose correlations bearing on specific industrial medical problems; but it is fair to assume that part of these differences are the result of variable standards of medical supervision. It is known, for instance, that the recent “flu” epidemic in certain plants caused an absenteeism of from 20 to 30 per cent, while in other plants where constant medical supervision was provided absence on account of sickness during the same period was held down to 7 per cent—a result which was directly attributed to hygienic standards which contributed to disease resistance, a smaller percentage, therefore, being afflicted, and the deaths naturally much lower than where such safeguards were lacking.

The average executive in modern industry has not been

slow to recognize the accident factor in his cost, but very few have counted the economic loss incident to neglect of health matters. While much emphasis has been placed upon accident prevention and safety devices, relatively little attention is being given to the prevention of lost time from illness which in the aggregate costs industry seven times as much as lost time from accidents.

It is not only in reduction of overhead that a consistent health program commends itself. A not inconsiderable by-product of the accident campaigns in industry has been the advantage gained by this means in the matter of better relations. Lost time from illness costs industry seven times as much as lost time from accidents. We believe that the same ratio obtains in the opportunities provided for the cultivation of better relations in the contacts afforded through medical supervision. It may be held that these contacts are provided through the Workmen's Compensation Act, but the average workman's attitude toward surgical service under the Workmen's Compensation Act is that such service, being compulsory, the employer is not entitled to any particular return in good will for this expenditure except when unusually extensive service is provided.

In the medical supervision of the industrial worker, however, the workman derives something he cannot purchase. As a matter of fact, our personal relations with our own physicians do not afford the same advantage of the constant accessibility the workman has to his physician during working hours. If medical supervision is provided, from 3 to 5 per cent of the shop force will seek its service every day in the year. Experience suggests that less than 1 per cent of the service so rendered is not well expended, but improvement in organization will take care of this. Preliminary interviews with nurses and other attendants may be depended upon to protect the physician from unnecessary interruptions, but if the average workman can reach through industrial medical service the type of physician in whom he can repose confidence, the sort of man he would seek out for himself on the outside, one whose interests include not only the workman himself, but the members of his family, and who will see in such contacts the opportunity to show sympathetic appreciation of the man's personal and family health problems, then in truth does industrial medicine become the most effective means of promoting the public

health. It will conserve the man's interest even ahead of that of the company, if the situation should demand it, and will effectually build up human relations and a shop morale founded upon fundamental necessities.

It is time for industry to recognize that the cost of illness in the plant as well as unnecessary sickness in the community is, in the last analysis, a load upon industry itself. Industry is the source of wealth, and from that source must be paid all losses from accident, disease, and death that might have been prevented.

Finally, it is for the executive to realize that effectual health supervision resolves itself into a question of personnel. In many industries where a cheap designer, a

cheap production man, or a cheap salesman would not be considered, it seems not to be at all appreciated that it is false economy to hire a cheap physician who will, of necessity, design a low grade medical service. That type of service is no more acceptable to the workmen than a poor product is to the public. One of the sad sights is to see a plant dispensary physically well equipped, but professionally under-equipped, where the poor service is recognized and is not sought by the men. In too many instances the plant executive has fooled himself into the belief that he has provided a worth while service and that the men, on the other hand, are ungracious enough not to appreciate it.

EDITOR.

SEATING OF INDUSTRIAL EMPLOYEES

BY HENRY LING TAYLOR, M.D., SECRETARY, AMERICAN POSTURE LEAGUE, INC., NEW YORK CITY

THE subject of output is the burning question of the day. Output depends upon method, organization, and supervision; but it also depends in large degree on the morale and physical well being of the employee. The employee must feel fit and, if possible, energetic and ambitious. He needs to be in good health, trained to his job, and must not be overcome by fatigue or worried by the monotony of his work. He must feel that he is getting a square deal and that whatever he can contribute to the output is for the benefit of all. In a word, he must have the cooperative spirit.

The avoidance of undue muscular strain and fatigue by habitual good postures, and by change of posture, are important factors in reducing industrial waste on the human side, and even in rendering accidents less frequent. On the whole, factory work done seated, when possible, is less fatiguing than work done standing, the alternation of the two being desirable, as a change of posture from time to time is extremely important.

In work done seated it is very important that the seat should not only fit the worker but also be adapted to the work. Some occupations require a high stool or seat, and in some the back of the seat can be omitted. In occupations which do not permit the feet to rest easily on the floor, a foot rest should always be provided. Some machines where the work can best be done seated are so constructed as to make a comfortable method of seating difficult, a condition which should be avoided in designing machinery. In working at objects on a moving belt, clearance for the knees should be provided below the moving belt. *Even when a proper seat has been provided, the worker must take pains to work in good posture with straight back, in order to avoid the evils of bent-over posture, which hinders the proper action of the lungs, heart, and other organs.* It is very important that chairs and benches be properly adapted as to height, that the seats be of the proper width, depth and slant, and hollowed at the back where the seat bones rest. If there is a back, the support should be properly shaped and placed at the right level, and there should be a wide space at the lower part, so that the worker may sit well back. When expert attention is given to the seating of operatives, the work will be more easily done and the output should be increased.

Seats adapted to the worker and to the work in hand reduce fatigue, backache, and add to the morale and efficiency of the workers. The subject is a new one and is only beginning to be appreciated and studied in indus-

try. From a purely practical point of view the comfort, health and happiness of employees is an asset.

As the tendency of modern industry is toward monotony and lack of variety in the postures and movements of the worker, these must be actively considered in laying out the work and, in addition to posture and seating, such questions as forenoon and afternoon recesses, hours of work, recreation, and kindred matters call for recognition in the up to date factory or shop.

Correct seating should provide such an anatomic shaping of the chair or stool that good posture is encouraged and made the comfortable position, whether one is active or resting. Most chairs are in themselves fatiguing, as they do not sustain the body in its correct posture. They strain a few points, and omit proper support of others.

The American Posture League, after painstaking study, has adapted and applied the following principles to various types of furniture, including factory seats:

(1) The pelvic seat bones should rest in a pocket or depression in seat floor, which will sustain the pelvis in its right relation to the spine and distribute the pressure borne by pelvis and thighs. In most chairs the seat bones of the pelvis bear the major part of the weight.

(2) The thighs should be supported at a higher level, from the pelvis to within a few inches of the bend of the knee, pressure on which should be avoided.

(3) The front edge of the seat should be rounded to avoid undue pressure on the nerves and blood vessels at the bend of the knee.

(4) The back of the chair should provide space for the buttocks and their coverings, both laterally and vertically; it should sustain the spine in correct relation to the pelvis without pressure on the bony spine or pelvis; it should be properly shaped for a wide range of sizes and types of back without the need of adjustable devices.

(5) The horizontal supports of the back should avoid pressure from sharp edges and should be correctly spaced as to height in relation to the shoulder blades.

(6) The back support should be free from pronounced curves (hollows) in the region of the shoulders, as these are a mould for round shoulders.

(7) The height of the seat should sustain to the working surface such a relation that there is room for the knee under the latter, and opportunity for the play of the arms at the elbow height.

(8) The height of the seat from the floor should be such that foot rests will give variation in height and place all in a proper relation to the working surface.

FRACTURES INCIDENT TO OCCUPATION*

BY JOHN J. MOORHEAD, PROFESSOR OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, NEW YORK CITY

WE ARE accustomed to believe that certain occupations are inherently dangerous to life, limb, and health and for that reason seek to erect safeguards by various methods which are well known. We have reached in various branches of medicine what might be called the age of prevention; we seek to attain that goal in various branches of surgery also. Malaria, typhoid, and yellow fever are now recognized as preventable maladies.

Pulmonary tuberculosis, and other diseases almost as rampant as the "white plague," will some day become as uncommon as was typhoid fever among the soldiers in the late war. Cancer is the one great menace yet unchecked and my belief is that the war has set us back many years in the conquest of this foe which was being fought hard in the laboratories and clinics the world over. Doctors and scientists of all the civilized world were temporarily deviated from their accustomed work by the onset of war and their labors were centered in caring for the injuries and accidents incident to the greatest occupation the world ever saw. The injuries of this temporary occupation called war were practically wounds and fractures and, despite the concentration of medical thought and study of these two problems, no radical departures from established principles can be recorded, and no strikingly new method has resulted that will help us in our management of the accidents and injuries of peace time. Certain advances have been made, but they were applicable in the main to military and not to civic activities; they could be put into use for military but not for industrial warfare.

The "Big Four" Causes of Accidents

Industry has always been regarded as the primary cause of accidents, and it still retains that position, but in recent years the extensive use of automobiles has made travel accidents a very close competitor. In certain non-industrial communities, the ordinary accidents and injuries incident to every day life scarcely afforded the physician an opportunity of caring for that large group of the injured which physicians in industry so often encountered. But the accidents incident to automobile usage have changed all this and now physicians the country over are brought into direct contact with this new element in their practice. In my own city of New York automobiles are now productive of so many accidents that their use has practically created what may be almost called an occupational hazard. Industry, transportation, mining, and ordinary mishaps now constitute the "big four" in the causation of injury.

In a broader grouping we may say that injuries occur as the outcome of pursuits, indoors and outdoors; they are the outgrowth of work or play; they arise from gainful pursuits or occur as ordinary hazards.

In these post-war days of stress, accidents are increasing; their severity in industry is lessening, but is rapidly increasing elsewhere. In this diminution, such organizations as the American Association of Industrial Physicians and Surgeons and the National Safety Council have taken a place in which they may well take pride. In a very large sense the entire metropolitan community

is engaged in some form of "occupation" and it is in that sense that I attempt to speak in my theme: "Fractures Incident to Occupation."

For descriptive purposes we may say that fractures are of minor, moderate and severer grades, not in the quantitative sense of the size of the broken bone, but in the qualitative sense of the damage done to osseous and soft tissues. A compound comminuted fracture of the right index finger may be more serious to a mechanic, a stenographer, a pianist, than a fracture of the thigh in the same individual. A laborer, a fireman, a policeman may be crippled by a fractured ankle, but a broken skull in the same individual may in no wise affect earning or productive capacity. However, a high official of one of our allied countries was recently forced to go out of office because of a minor fracture of the skull, although a crippling injury of several limbs would have permitted him to remain the honored incumbent of high official position.

In other words, we can say that the severity of a fracture is inversely dependent upon the occupation and not upon the severity of the injury. With this mathematical basis in mind, we are enabled to estimate the potential possibilities of a fracture not upon the initial severity but upon the probable outcome in terms of deformity or disability.

This brings us to the problem of treatment; for, after all, the diagnosis is no longer hidden in this day of universal x-ray usage. In passing let me say that we place too much reliance on this means of diagnosis; we use our eyes and our fingers too little; we are losing our inherent special senses from atrophy of disuse. Let us employ our special senses more for diagnosis, reserving the x-ray to determine the success of our attempts at reduction.

There are certain simple principles of treatment to guide us. These are pre-Hippocrates in origin, ages old in application. The styles of splints change almost as often as the clothes we wear; but, like our clothing, they cover (or uncover) the parts beneath.

There are four essential principles in fracture treatment—the four R's I call them. They are (1) Recognition or diagnosis; (2) Reduction or setting; (3) Retention or splinting; and (4) Re-education or functioning. Of these the second—reduction—and the fourth—re-education—are the most important. Briefly permit me to set forth some of the cardinal factors in each of these four groupings.

Let us at the onset first determine that we have a fracture and not a contusion-sprain or dislocation. If we are in doubt, let us treat our case as a fracture until we prove to the contrary. We may well invoke the doctrine of probabilities in reaching our conclusion, notably in respect to joint injuries. Almost 99 per cent of deforming and disabling injuries of the hip joint are fractures of the neck of the femur and nothing else. In the wrist and ankle, this proportion is about 85 per cent. In the smaller joints, like the fingers, fracture, not dislocation, not contusion-sprain, is the ultimate diagnosis. If we will remember this, we will less often have rude awakenings in our hip, ankle, wrist, and hand injuries. Let us realize also that basically there are only two classes or types of fractures, either of which may be simple or

*Read before the American Association of Industrial Physicians and Surgeons in joint session with the Health Section of the National Safety Council, Milwaukee, Wis., September 29, 1920.

compound. Type I is the displaced form in which the fragments are unapposed. Type II is the non-displaced form in which the fragments are apposed. In Type I we must not only reduce our fracture but also retain it; but in Type II we need only retain it. This clarifies the situation to a considerable extent; it makes us realize that in some cases we do most when we do least.

Methods of Reduction or Setting

This phase of treatment applies to Type I only. Let us realize that efficient reduction is the key to success and that splints, however modern or elaborate, will not of themselves aid reduction in the slightest. This cannot be emphasized too strongly, because too many of our cult believe that a splint of fancy name or fancy form will work some magic change in the hidden bone. A splint only helps to keep the part in the position in which we place it; no splint of itself ever set a fracture.

We must get in the habit of using anesthesia more often as an aid to reduction. Nitrous oxid is the safest and best for ordinary use. Ether or ethyl chlorid are the next choice; but chloroform is very dangerous in any accident case. Begin every act of reduction by making the original deformity worse to loosen fragments and stretch the soft parts. End every act of reduction by overcorrecting the original deformity. Absolute relaxation is a necessity because displacement of bone is due alone to abnormal muscle pull and we correct our bony mal-alignment by restoring mal-aligned muscles. In no joint fracture is muscle pull more potent than in Pott's fracture and, unless we fully relax the tendo-Achilles, our efforts may fail. To do this the best way is to fold the thigh fully on the abdomen and then make traction with the limb in that position. There are certain cases inherently impossible of reduction without open operation or skeletal traction. Let us recognize these and not waste time attempting what experience tells us is impossible. In this group, personally, I place certain fractures of the thigh, of the lower leg, of the forearm and of the os calcis. I advise operation in fracture of the olecranon and the patella provided the patient has the physique and the surgeon the technic. The introduction of buried foreign matter like plates, screws, and wire is only most exceptionally needed.

The first requisite of a splint is safety, the next security. Moulded plaster of Paris should be used in that class of case in which we ordinarily choose a circular cast. The latter are dangerous and they prevent ready inspection, hence do not permit early massage and motion. Thomas splints are excellent for the lower extremity, especially for first aid treatment. The Jones arm splint is an excellent device, also; but each of these requires constant supervision and for that reason are most useful in hospitalized cases. My routine for fracture of the neck of the femur, in selected cases, is the plaster of Paris abduction splint. For fractures of the thigh elsewhere, the Steinmann nail or the calipers (ice tongs) is the method of choice. For the lower third of the leg, the stirrup of Finochietto is the choice. Forearm fractures—irreducible by two attempts under anesthesia—are cut down and forced into place by jamming the fragments or holding them in place by kangaroo tendon. For non-union, autogenous bone grafting is the usual necessary measure.

Too tight or too loose splintage is, next to non-reduction, the most usual cause for failure of the fracture to unite and, accordingly, must be guarded against. Here, again, moulded plaster of Paris is very helpful for in effect this is the custom-made splint that is designed to

fit the patient, unlike the ready-made splint to which the patient is fitted.

Re-education or Functioning

This, as stated, is the most important phase in treatment, reduction being of all the most necessary. Early massage and early motion should be part of our therapy and the nearer the fracture to the joint, the earlier these may begin. The foundation of this part of our treatment is the recognition that in the pathology of a fracture, the osseous damage is only the cause of the lesion, and that the soft tissues—muscular, tendinous, articular, vascular, and neural—usually share in the composite picture.

In a Colles' fracture, for example, massage begins the day after the injury, passive motion on the fifth day, active motion on the tenth, all splints off at the end of the third week. In every joint fracture the early use of massage and motion means less stiffness, less atrophy, less weakness when union has become firm. In the lower extremity fractures, especially of the thigh, the use of walking calipers, made from a Thomas splint, will get the patient out of bed, will exercise muscles, promote circulation, and restore functions nearly 50 per cent more promptly than by the older methods. Physiotherapy is a sovereign aid toward recovery and no longer can we regard our patient as cured until function is restored. When we return our patient to the occupation from which he came, then and only then should we regard our duty fully done. Cooperation from our patient is a great asset, for without that it is impossible to attain the safe and speedy outcome we now seek to attain.

As to compound fractures, we now aim to convert them into simple fractures by applying the war lesson of sparingly cutting out all the damaged soft parts, suturing or partially suturing, in the knowledge that by this method of controlled débridement we can combat infection and in effect make of our open a closed fracture.

The Matter Concluded

Briefly, we have tried to show that the occupation of the patient is a main factor in the situation, irrespective of the gravity of the fracture. We have tried to stress the importance of reduction and re-education as essentials in determining the outcome.

We realize that there are two types of fractures, only, and that the treatment of one is often difficult, the other easy.

We recognize certain fractures as being in the "irreducible" class and in these we do the operation of open correction or use the Steinmann, the tongs, or Finochietto procedure.

We begin massage and motion early, not forgetting the physiotherapy will often give us an excellent result when the contrary appeared likely.

We convert selected cases of compound into simple fractures by the process of débridement.

Finally, we recognize that a fracture is a problem in major surgery, that the possibilities of crippling are inherent, that it often requires more skill and experience to obtain real recovery than in many abdominal operations. Traumatic surgery is not always spectacular, it will always appeal only to a certain class of physicians, it is becoming a specialty of its own, and in the recognition of its importance industrial surgeons have taken a prominent part.

Wage earners lose 250,000 working days a year because of illness, much of which is preventable.

CHRONIC CARBON MONOXID POISONING—ITS IMMEDIATE AND SUBSEQUENT MANIFESTATIONS*

BY GEORGINE LUDEN, M.D., PH.D., FIRST ASSISTANT IN PATHOLOGICAL RESEARCH, MAYO CLINIC, ROCHESTER, MINN.

THE symptoms caused by chronic carbon monoxid intoxication depend on the capacity for elimination of the poison possessed by the victim, on the time of exposure, and on the amount of gas inhaled. In common with many other toxic compounds, carbon monoxid furnishes symptoms of excitation and of depression, the latter resulting from exhaustion of the organs which first respond by increased activity; hence the kaleidoscopic variety of symptoms produced by chronic CO poisoning. Alcohol intoxication offers some interesting points of similarity, as it also produces excitation, somnolence and a comatose condition. It is well known that one man is intoxicated by a small glass of liquor, while another not visibly affected by ten times that amount; one man while intoxicated becomes irritable, pugnacious, another tearful and depressed, and a third excitable but hilarious. These totally diverse effects of alcohol have not, as far as I am aware, been associated with the response of different endocrine glands in different persons. The divers effects of carbon monoxid can be thus correlated in the light of our present knowledge, as will presently be shown.

For the sake of convenience I shall refer the manifestations of chronic CO poisoning observed in this series to three periods.

The first period—September-October, 1919, covering the inhalation of unknown, variable amounts of carbon monoxid, produced as subjective symptoms: a tingling, contracting sensation in the fingers and toes, similar to the pins-and-needles in a foot that is "going to sleep"; spontaneous twitchings of one finger or toe; numbness of face and scalp with the sensation of a tight fitting cap on the head, not giddiness, but recalling the drying of "New-Skin" on a cut. (I have been told that the beginning of ether anesthesia gives a similar sensation); an increasing feeling of weight in the chest; breathing an effort and the chest wall seems to be heavy and difficult to move; a sensation of weight and impeded heart action; the heart beats with an effort—at times it seems to falter, but recovers shortly after.

Well defined objective symptoms were present: sudden transient pallor ("changing color") and at times more persistent greenish pallor; dark red lower lip, in sharp contrast to upper lip and gums of natural color; red patches on the cheek bones in which minute veins are sharply marked, these red patches and the bluish-red lower lip forming a vivid contrast with the pallor of the face. In some persons the cheeks are of an abnormal intense dusky red. The whole eyeball has a peculiar "shiny" or glittering appearance; at times the demarcation between the pupil and iris seems somewhat blurred, giving the eye a "washy" look. Even at this period I only saw the enlargement of the pupils at very rare intervals, and as my patient was in pain at those times pain was naturally assumed to be the cause. The veins of the hands are strikingly narrow and dark, almost black, recalling anatomical drawings in India ink. Acute central abdominal cramps occurred with visible muscle spasms. Bladder symptoms were evident as pain in the bladder, difficulty in starting micturition, sudden pressure of urine, much very pale urine being voided at times, the urine being nor-

mal as a rule. There were: transient "fainting spells"; shivering attacks without temperature; general muscle "soreness"; lassitude on waking; nervous irritability or depression ("the blues"); and transient sore, "raw" throat.

As the variable amounts of gas were produced by changes in the wind and other factors from time to time, these symptoms naturally varied in intensity. The feeling of numbness in the feet increased to a sensation of weakness. The rigidity of fingers and toes—preceded by neuralgic pains—is the terminal stage of this numbness. The sensation of weight and oppression in the heart and chest gradually develop into dyspnea and syncope. The reaction produced spontaneously after inhalation of small amounts of gas, or by camphor, is accompanied by shivering that cannot be controlled by will power and makes the victim feel extremely foolish. After a severe attack of shivering the feeling of utter exhaustion is such that no determination or habitual self-control avail to prevent an undignified manifestation of tears and one seriously decides that dying would be pleasant. This happened to me on two occasions.

During the second period—November-December, 1919—the recognized, but unpreventable production of carbon monoxid in small amounts caused as subjective symptoms: great fatigability, any exertion, muscular or mental, producing exhaustion and a kind of "inside" tremor; marked shortness of breath on exertion, with racing pulse; extreme chilliness. The hands feel ice cold and lifeless, subjectively and objectively. It is impossible to get warm even in front of a roaring fire. The heart felt "weary," like an aching weight in the chest, at times the dull ache changing into a cramping pain, as if the heart were compressed in an iron grip; or the dull ache is interspersed with small, sharp, shooting pains, resembling the biting of some small animal. These cardiac irregularities cannot be made visible by the electrocardiograph, even when felt most acutely; they are probably caused by vascular spasms.

Objective symptoms present as: sudden uncontrollable drowsiness, causing sleep in the middle of a general conversation; shivering attacks without syncope and without rising temperature; short spasming of individual muscles; extreme thirst (our thirst was quenched only by drinking tea in great quantities; no other beverage had any effect); a great craving for sugar, which we ordinarily disliked; transient bronzing; a peculiar, transient "shrinking" of the face which temporarily looks pinched and old, for from twenty-four to thirty-six hours; low blood pressure with normal pulse pressure (25 to 30 mm.). Transitory "uncomfortable" heart action; irregular "flattening" pulse; and respiratory oppression after the intake of food, followed at times by slight shivering attacks; low blood sugar values. There were no other demonstrable findings.

During the third period—January to December, 1920—hypersensitization to minute amounts of carbon monoxid was so marked that a whiff of exhaust from a passing automobile, smoke from a neighboring chimney, traces of carbon monoxid in houses heated with hot-air furnaces, checked by many observations, were manifested by sudden acute, transient nausea; numbness of the feet which as-

*Part I of this article appeared in the February issue.

cended to the knees but extended no further; numbness of the face and scalp—the scalp felt too tight. These symptoms soon pass off, but they are invariably followed in from twelve to thirty-six hours by the following corroborative symptoms: pains in the feet, hands, or scalp (scalp headache), the veins being visibly narrow and dark in circumscribed areas. The area feels like a bruise but shows no subsequent discoloration. Beyond the contracted area the vein is engorged and of normal color. When the vein spasm relaxes the contracted portion of the vein is objectively *increased* in caliber and bulges somewhat; then the pain disappears. The same behavior of the scalp veins (though invisible) is probably responsible for the scalp or “coal gas headache” which I always get after exposure to traces of carbon monoxid. This headache is very characteristic; its character never varies. It is circumscribed to a small area of the scalp, which becomes sore to the touch. It is very intense, can be made to shift somewhat, but not to disappear, by rubbing, and cannot be banished by the usual remedies, aspirin, phenalgin, pyramiden. Morphin was not tried. It was checked to appear independently of any other headache-producing factor, does not incapacitate for work, and, though highly unpleasant, wears off in from one to several days. At times the dull ache in the heart region also appears. This syndrome has helped me to detect many unsuspected sources of carbon monoxid. There are no clinically demonstrable findings.

The following suggestions are submitted as having been found of value in my own experience with chronic carbon monoxid poisoning:

(1) Even slightly gassed patients should be watched constantly. “One can never be sure that an individual who is apparently only slightly affected will not pass into the second (syncope) or into the third stage (apnea) very suddenly, and *without premonitory symptoms*,” (McCombs).

(2) No patient suffering from carbon monoxid poisoning should be taken suddenly into *cold* air because there is eminent danger of collapse, and violent exercise should be avoided (McCombs). I can testify to the importance of this warning: the sensation of oppression and impeded heart action caused me to go out into the cold night air and walk a few hundred yards, when the symptoms rapidly increased to such an extent that I was on the verge of collapse, and camphor had to be given in a hurry (October 26, 1919). In carbon monoxid poisoning the entire organism works “with the brakes on”; the stimulation of cold air or exercise “speeds up” the body engine too rapidly, to the detriment of the machinery.

(3) Subcutaneous injections of camphorated oil give immediate relief from the sensation of respiratory and cardiac depression, even when these symptoms are mild. Calcium lactate, 15 gr. three times a day, reduces the severity and the duration of the attacks of shivering.

(4) Inhalation of oxygen mixed with 6 to 10 per cent carbon dioxid, recommended by Henderson and Haggard, is likely to be of great value. As this method of treatment was published only recently, I was not able to give it a trial. In cases of emergency it might be administered by a pulmotor. Henderson and Haggard showed that the blood of dogs gassed to unconsciousness and which contained 60 per cent carbon monoxid was practically cleared of the gas in twenty-two minutes by oxygen mixed with carbon dioxid, while the same saturation of carbon monoxid was eliminated in eighty minutes by inhalation of pure oxygen, and in one hundred and eighty minutes by inhalation of pure air.

(5) Organotherapy—dissicated total adrenal, or total

pituitary, by mouth—proved valuable to combat the after-effects in my experience. The dosage must be regulated according to the needs of the individual patient. Digitalis and tincture of Strophanthus also proved valuable in small doses; *Sajous* ascribes their beneficial effect to stimulation of the adrenal system. The after-effects of carbon monoxid poisoning coincide with the manifestations of temporary adrenal exhaustion, shown by the muscular weakness, circulatory weakness, and general asthenia.

The effects of carbon monoxid are not generally understood: namely, (1) its action on the red corpuscles, (2) the tenacity with which it clings to inanimate objects, and (3) the hypersensitization to carbon monoxid which follows chronic poisoning.

Carbon monoxid does not destroy the red corpuscles, as is still believed by many physicians and even taught in modern textbooks.¹⁴ The gas is merely carried by the corpuscles in the same way in which oxygen is carried; but carbon monoxid retains its hold on the corpuscles three hundred times longer than does oxygen (McCombs). A corpuscle laden with carbon monoxid cannot simultaneously carry oxygen: hence the oxygen transportation is reduced by inhalation of carbon monoxid. It is impossible to demonstrate carbon monoxid in the blood in non-fatal cases after pure air has been inhaled for three hours (McCombs). The gas is eliminated by the same process by which it was absorbed, that is by breathing (Henderson and Haggard). The Katayama test was negative in the blood of the fourth inmate of my house on the day when it was positive in three of us, because this girl had walked half a mile and had been at work for several hours after leaving the house before her blood was tested. Breathing is normally kept up by the carbon dioxid supplied by the vital processes. These processes are reduced by carbon monoxid, and too little carbon dioxid is elaborated adequately to stimulate the respiratory center. A vicious circle results: inhalation of carbon monoxid reduces both the oxygen intake and the carbon dioxid production; the respiratory center, deprived of its normal stimulus, decreases its activity, and the toxic gas, instead of being eliminated, is thus retained. The symptoms of carbon monoxid poisoning are chiefly the result of the oxygen deficit: they are many and diverse, because many and diverse tissues suffer; each tissue complains in its own peculiar way. The weakest organs in a given person naturally suffer most; hence the diversity of symptoms produced in different persons by chronic carbon monoxid poisoning.

The tenacity with which carbon monoxid clings to objects such as garments and furniture causes the gas to behave almost as if it were dust or some other finely powdered substance. I had the opportunity of observing this three times. While the furnaces were being overhauled in my house, my patient and her nurse stayed at a hotel, while I stayed with a friend. Clothes belonging to this friend had been hanging in an alcove in my house for many months; they were carried in a basket on a very windy day to her house, a distance of at least one hundred yards.

I observed that my friend looked rather pale when I returned from my work about lunch time; when the meal was finished she began to show the slight objective symptoms of carbon monoxid poisoning, dark red lower lip, red patches on the cheeks, and glittering eyeballs. She complained about difficulty in breathing and uncomfortable heart action. Her pulse showed the peculiar “flattening.” I made her take a spoonful of brandy and she immediately developed the characteristic uncontrollable shivering attack, which lasted about five minutes. These symptoms puzzled me not a little, as she had been in her

own house all morning, occupied in sorting the garments aforementioned; but after I had been in the room a few minutes where these garments were spread out, the windows being closed, I felt acutely nauseated; the concentration of carbon monoxid must therefore have been considerable. In the second instance a sweater belonging to my patient was the cause of carbon monoxid symptoms. It had been in her room at my house constantly during the first period of our exposure, and been put in a suit case in which it remained after she came to the hotel. The first time she wore this sweater she developed symptoms of carbon monoxid poisoning within ten minutes. After a thorough beating in the open air had removed the traces of gas the garment could be worn with impunity. Several days later a woolen baby blanket, which she began to knit at my house, was taken out of the same suit case. She had worked on it but a short time when she developed symptoms of oppression, with characteristic irregular pulse, which subsided as soon as the object was removed and did not recur after the blanket had been cleaned as if it had been covered with dust. I have been told since, that in the United States training camps during the war the trenches were cleared, after gas attacks, by means of canvas shovels with which the gas laden air was thrown out as if it had been snow; which helps to explain the curious phenomena which I observed.

The hypersensitization to carbon monoxid produced by exposure may be responsible for the effect which the small amount of gas clinging to garments was able to produce; it is comparable to the sensitiveness to ether observed in persons who have had ether anesthesia. It has enabled the discovery of minute sources of carbon monoxid production in innumerable instances, corroborated by closer investigations. Even today a whiff of exhaust gas from a passing car or an equally small amount of carbon monoxid produces in me the sequence of symptoms which I have checked many times. Since this sequence is produced even when unaware of the source of carbon monoxid production, mere association of ideas can hardly be responsible for the symptoms.

The subject of endocrine efficiency and its relation to chronic carbon monoxid poisoning is so vast that it can be considered only in the broadest outline. Nevertheless, its economic importance is such as to deserve consideration. Endocrine efficiency and economic efficiency are intimately related. The data collected by McGurn and my own observations point far more definitely to specific, often transient and reparable, injury to certain glands of internal secretion produced by chronic carbon monoxid poisoning than to indefinite undemonstrable changes, vaguely ascribed to the nervous system. Histopathologic changes in the central nervous system in one fatal case of carbon monoxid poisoning, have been reported *Stewart*; but the evidence submitted seems questionable, to say the least, as no data are given concerning the source of gas production; autopsy was performed thirty-nine hours after death, and, as *Stewart* himself admits, "syphilitic infection cannot be entirely excluded." The symptoms described by McGurn and many which I observed can be brought in direct correlation to many known and recognized manifestations of endocrine insufficiency, as may be seen from the following brief survey.

Thyroid.—Hypertension, dyspnea on exertion, tremor, headache, and ravenous appetite are among the recognized symptoms of hyperthyroidism. McGurn's patient (Case XX) developed these symptoms after exposure to soft coal smoke. They disappeared when the patient was inhaling pure air in the country, to reappear when she returned to her apartment exposed to combustion fumes. I have

repeatedly produced these symptoms experimentally in myself by ingestion of 6 mg. thyroxin (thyroid hormone). Nervous excitability and irritability are known to accompany hyperthyroidism. Exposure to carbon monoxid by accidental closing of the main furnace damper, which remained unnoticed for a week, produced these symptoms to a marked degree in a married couple whom I know personally and in whom the symptoms disappeared after the source of carbon monoxid production had been discovered and eliminated.

Parathyroids.—Muscle spasms and muscular rigidity occur admittedly in Parkinson's disease and in postoperative tetany resulting from removal of the parathyroids. In the latter condition calcium lactate is the medication of choice. The markedly beneficial effect of calcium lactate on the muscular spasms and uncontrollable shivering observed in my patient and myself during exposure to carbon monoxid suggests that these symptoms were the result of transient parathyroid insufficiency. The parathyroids are admitted to control calcium metabolism (McCallum).

Pituitary.—Polyuria and headaches located behind the eyes are symptoms which today are connected with disturbance of pituitary function (Timme). A relation between the activity of the pancreas and the pituitary has also been observed; pituitary extracts inhibit pancreatic secretion (Wiggers). In McGurn's patient (Case XIII) exposure to the soft coal smoke which had produced symptoms of hyperthyroidism in Case X, caused polyuria and a diabetic condition associated with 12 per cent of urinary sugar in a short time. This patient had been accepted as a Class A risk for heavy insurance by two insurance companies six months previously. The details of this case should be read in the original. Crowe, Cushing, and Homans observed profound somnolence, and Schäfer a marked diminution of body temperature after removal of the pituitary in animals. Ingestion of total desiccated pituitary raises the body temperature from two to three degrees Fahrenheit (Sajous); I have verified this by taking pituitary experimentally myself. It is obvious that pituitary exhaustion may be expected to produce in a minor degree the symptoms caused by removal of the gland. For several weeks after our prolonged exposure to carbon monoxid my patient and I suffered at intervals from such intense drowsiness as to be overcome by sleep in the midst of a loud general conversation. The peculiar "shrinking" of the face, which makes it look temporarily pinched and old, may also be connected with an initial hyperactivity of the hypophysis, since Hoskins and Hoskins found that pituitary feeding produced a similar picture in frog larvae. Although starvation had been carefully excluded, the pituitary fed animals assumed temporarily the appearance of "starved tadpoles." The emaciation appeared within forty-eight hours but disappeared in a few days; while it lasted, the tadpoles were sluggish in their behavior; afterward they showed a high degree of irritability: "the slightest jarring of the aquarium starts them all to swimming about very actively." The severe subjective and objective feeling of cold from which we suffered may have been connected with pituitary as well as with adrenal insufficiency, since, as Sajous has pointed out, removal of the pituitary produces symptoms similar to those following removal of the adrenals (Sajous). The histopathology of the pituitary in lethargic encephalitis has, strange to say, received no consideration so far.

Adrenals.—Muscular asthenia, circulatory weakness, hypotension, chilliness, nausea, a tendency to fainting spells, sudden exitus from cardiac failure, bronzing, and

abnormally low blood sugar values are the symptoms of adrenal insufficiency enumerated by Sajous and found in Addison's disease. Transient manifestations of Addisonia were observed by Carles in men who had been gassed during the war. The cardinal symptoms of carbon monoxid poisoning coincide with those of adrenal insufficiency. After our exposure to carbon monoxid my patient and I presented the objective symptoms of transient bronzing, low blood sugar, and hypotension as well as the subjective symptoms of muscular fatigability, chilliness, and uncomfortable and irregular heart action.

Timme has called attention to the endocrinologic aspect of neurologic conditions such as neurasthenia, migraine, and epilepsy. Williams pointed out, as early as 1915, that the manifestations of neurasthenia are those of adrenal insufficiency. I have endeavored to show that the symptoms produced by chronic carbon monoxid poisoning may be interpreted in the light of our present knowledge concerning the glands of internal secretion. Only careful inquiry into the living conditions of patient enables the physician to detect and diagnose chronic carbon monoxid poisoning, as McGurn has proved. If, in the absence of demonstrable findings, the vague and meaningless diagnosis, neurasthenia, were discarded in favor of a more modern term—such as endocrinopathy—and the living conditions of the patient taken into consideration as well as his symptoms, many unsuspected instances of chronic carbon monoxid poisoning would be revealed to the credit of the physician and the comfort and benefit of the patient.

Relation to Social and Domestic Problems

The imperceptible way in which carbon monoxid undermines the vitality, its ubiquity in modern life, the diversity of its effects, which, according to the relative endocrine integrity of the victim, causing nervous irritability in some and mental depression in others, are well calculated to make this insidious poison a potent factor in social and domestic problems. It may not be a mere coincidence that discontent and social unrest are prevalent among those whose occupation implies constant exposure to varying amounts of combustion gases: round-house men, who are surrounded by the smoke of locomotives; longshoremen, exposed to the combined smoke of engines, steamers and cranes; building trade workers, who inhale the large amounts of carbon monoxid produced by "building furnaces" and the "salamander stoves" used to accelerate the drying of newly constructed buildings.

In domestic life the inhalation of traces of carbon monoxid produced by inadequate gas fittings or slightly defective furnaces, especially hot air furnaces, may be the cause of far more domestic disharmony than has been realized. A striking instance came under my personal observation. My exposure to carbon monoxid has "sensitized" me to the effect of "coal gas"; twelve months of careful observation have taught me to recognize its first slight manifestations. A short stay in the house of friends invariably produced in me symptoms which I had learned to associate with the inhalation of small amounts of carbon monoxid; namely, an increasing feeling of numbness in my feet and face and slight feeling of constriction in my chest, followed several hours later by pains in arms and legs, scalp, and in the region of the heart, and extreme weariness, together with that type of despondency which is commonly known as "the blues." These friends refused to credit the production of any carbon monoxid in their houses, but on three different occasions, at several months' interval, my suspicions of the presence of the gas were proved to be correct. The first time the main damper of the furnace connected with

the hot water system was found to have remained closed for a week after being repaired. The second time the iron breeching was found to be corroded; the third time a chance remark revealed the fact that a small furnace for the hot water supply had been installed recently. This furnace had been connected with the single flue used by the central heating, thus duplicating the conditions which had led to the production of carbon monoxid in my own house. During these weeks both husband and wife had admittedly not felt well; the husband was troubled with frontal headache, attributed to sinusitis as an after-effect of influenza; the wife slept badly and was in a very irritable, aggressive frame of mind. She had attributed her weariness and irritability to the "strain" of housekeeping; and domestic harmony was conspicuous by its absence. Since then, domestic happiness has been restored completely by structural changes in the chimney which provided a flue for each furnace, and by the installation of new iron breeching (Figs. 4, 5, and 6).

These instances may suffice to call attention to the relation between slight chronic carbon monoxid poisoning and many hygienic, social, and domestic problems. It may well be deduced that "hot air" furnaces are responsible for much unhappiness as well as ill health, and the quaint remark of a fellow physician, "in divorce suits inquire after the gas fittings," may contain more truth than fiction.

INCREASE HOSPITAL APPROPRIATION

The Senate added \$1,100,000 to the appropriations for the construction of hospitals for wounded and disabled soldiers during its debate on the Sundry Civil Bill. The hospital at Fort Bayard, N. M., was allowed \$750,000; the Marine Hospital at Evansville, Ind., \$100,000, and the Marine Hospital at Pittsburgh, \$250,000.

HEALTH OF TELEPHONE WORKERS—A SUMMARY*

THE last published report of the Bureau of Women in Industry of the New York State Industrial Commission was made available to the public in July, 1920. It is a study of the telephone industry, made at the request of the Governor because during the year 1919 the telephone service, which had been almost above criticism, had deteriorated to such an extent that business was crippled and the public seriously inconvenienced.

The Bureau undertook an investigation of the conditions of employment for women in the telephone exchanges throughout the state with special reference to wages, hours, labor turnover and its causes. The women employed by the telephone company in New York are not subject to any of the regulations of the New York State labor laws. Moreover, telephony represents an industry which must render the public a twenty-four hour day service.

Scope of the Study

The study was limited to cover 12,326 operators, some two-thirds of the girls employed in the exchanges of the geographical division of the state. Prior to this report of the New York State Industrial Commission, two studies of importance had been made. The first was published in 1907, and was a report of the Royal Commission on a dispute respecting hours of employment between the Bell Telephone Company of Canada and the operators of Toronto, Canada. This dispute hinged on the point that the working time of the operators was to be lengthened from five to eight hours, the operators contending that it was a physical impossibility to stand such long hours. The company at that time refused to deal with them in any way, and a strike was threatened, which threatened to affect so seriously the interest of the public that the Canadian Government stepped in to settle the dispute.

The second investigation was that of the Department of Commerce and Labor of the United States Government in 1910, after a resolution was introduced into the senate asking that investigation be made of the telephone companies engaged in the conduct of interstate business as to their method of business, wages, hours, etc. Both these reports threw considerable light on telephony, and are significant in that these official bodies at that time argued that the wages of the workers were too low and the hours too long.

As a result of the New York investigation, the Bureau of Women in Industry made the following recommendations, these recommendations being grouped under two general heads:

(1) Reduction of labor turnover. A telephone operator is not a real asset to the company until she has been with it for one year. Therefore, every effort should be made to retain the operators.

(2) An increased number of operators. Traffic has increased 27.5 per cent from January, 1919, to January, 1920. It is necessary, therefore, that the number of operators increase proportionately to the increase in traffic.

Remedies Recommended

As means of meeting the problems presented by these two factors, the Bureau of Women in Industry would therefore recommend:

(1) Scientific selection of suitable operators by the Employment Department in order to decrease the labor turnover within the Training School itself.

(2) A reorganization of labor management, so that the same department, preferably the Employment Department, is responsible for employing, dismissing and accepting resignations of operators, thus securing coordinated methods of handling labor supply.

(3) The limitation of the number of working days to six.

(4) Compulsory rest periods of fifteen to twenty minutes at reasonable intervals for every operator, preferably splitting the trick to two equal parts.

(5) The elimination of all overtime, and the gradual establishment of a seven hour shift for the day and night operators similar to the seven hour shift for evening and split-trick operators.

(6) A higher maximum wage rate, and a faster rate of promotion for an employee who has been in the service for two years. Increase in wage, after this period, which marks the beginning of 100 per cent efficiency, should be such that it will be an incentive to remain with the company.

(7) The extension of the facilities of the Medical Department to give operators periodical physical examinations with particular reference to nervous strain and its effect on health and efficiency. In order to make this effective, complete medical records for each employee should be kept.

(8) A democratic system of organization and representation among the employees, through which they may express their desires and by which they may acquire a sense of responsibility toward their work.

The Bureau of Women in Industry would recommend further:

(1) An amendment or amendments to the Labor Law which shall include telephone exchanges as subject to the supervision of the Industrial Commission as prescribed for factory and mercantile establishments under Section 51-a of the Labor Law.

(2) The serious consideration by the Public Service Commission of the items in this report which have a bearing upon the much complained of inadequacy of the telephone service, with such action to remedy these defects as is possible under its broad powers.

Fatigue Study Not Made

It was not possible for the Bureau of Women in Industry, in the short time allotted to it, to make any scientific study of the results of fatigue involved in operating a telephone switchboard. The Bureau strongly commended that the Medical Department of the Telephone Company be utilized to make a thorough study of the effects of telephony upon the constitutions of women operators and the possible effects upon their children.

It is undoubtedly true that a telephone operator is subjected to constant strain. The company has attempted to reduce the physical strain of stretching and reaching by limiting the size of the board which the girls operate and by adjusting the height of the board so that the girls may either sit or stand at intervals. The company has also adopted a policy of rest periods requiring a fifteen minute break during the first half of the day's service and another fifteen minute break during the second. When there is a shortage of labor, however, or work is particularly heavy, rest periods are not always to be had. In view of the testimony of the medical authorities of Toronto in the study of telephone operating made by the Royal Commission, the Bureau considers the strict observance of rest periods imperative.

One of the significant points in the report is the need for closer cooperation of the medical with the other departments. The standards for "loads"—the number of calls an hour—which the operator handles have apparently been worked out with the emphasis largely placed on the

*A report submitted to Alfred E. Smith, governor of the state of New York, prepared by the Bureau of Women in Industry of the State Department of Labor, New York, July, 1920.

degree of efficiency and speed possible from each position, and little consideration has been given to the human element. The scientific measurement of fatigue of the operator should certainly be considered in relation to scientific measurement of a possible "load." Though it is true that the ordinary methods of measuring fatigue are of little value in the telephone industry because of the large personal factor involved, the possible emotional strain from dealings with irritable subscribers, uncongenial supervision, etc., these very difficulties make the study of the problem all the more essential.

The work of telephone operating under any conditions entails some strain on the nervous system; the faculties are kept constantly on the alert, there is high tension on the special senses, and a certain amount of mental worry. The strain is in proportion to the nervous force exhausted, and exhaustion is a matter only of degree depending upon the duration and intensity of employment. Telephone operating differs from most other occupations in which women are employed in its call on the special senses of sight, of hearing and of speech. Even when not actually busy, operators are not resting or relaxing, because they are necessarily on the alert. The impatience of subscribers is also an important cause of nervousness. With each call a light flashes in front of the operator, several of these lights flashing simultaneously show that a number of subscribers are calling for numbers at the same time. The operator is expected to give the quickest possible attention to each, and to remember which light flashed first. When several signals come at once, and others come before these can be cared for, the order is necessarily lost and her effort is concentrated on clearing the board. When an impatient subscriber jiggles his receiver he not only flashes the signal light in front of the operator, but when the operator opens her key to learn his wants, a clicking sound is caused in her ear every time the subscriber moves the receiver up and down.

Consciousness that a number of subscribers are waiting to have their calls attended to, their growing impatience emphasized by the constant flash of lights before her eyes, and the incessant buzzing in her ears, together with the knowledge that the supervisor is standing behind her either hurrying her or asking other operators to attend to her numbers, and the observer may plug in to criticize at any moment, causes strain which might in some degree be lessened if subscribers learned to be a little more patient.

The operator is allowed to respond in certain set phrases, such as "Number please," "Excuse me please," etc. She may not "talk back," no matter how much she is being abused by a subscriber, and any abuse which the subscriber may heap on the operator only delays her operations and clogs her switchboard.

Supervision Unsympathetic

Another cause of strain is undoubtedly the system of supervision. One of the most common complaints and criticisms of the telephone company as expressed by the operators, was that supervision was unsympathetic and over-strict.

For every eight to ten girls there is a supervisor, walking back and forth behind their chairs, assisting in handling calls when necessary, and helping in the adjustment of difficulties. The assistance the supervisor renders the operators is incalculable. Her presence, however, adds materially to the mental and nervous strain of the operator, especially if she herself is nervous and irritable. The continual presence of a supervisor, if she is not a person of understanding and sympathy, creates in itself an element of nervous strain.

The position of observer is a second supervising position. There are fewer observers than supervisors and they are not visible to the operators. The observer has a board which is called an observation board and from which she can plug in on any operator, follow her work

in detail, time her calls, hear her remarks, and also those of the subscriber.

There is no doubt that close supervision is necessary. It is true, however, that this close double supervision which the company gives the girls plays a very large part in the nervous strain on the operator. One supervisor has been reported as walking back and forth behind her nine or ten girls saying in low, monotonous voice, "Hurry girls, hurry girls." With a girl answering calls as rapidly as possible, and with lights flashing in front of her eyes continuously, and the buzzing in her ears, the fact of being driven from behind irritates many of the girls to the extreme.

The telephone company has attempted to establish a six day week for all operators with an eight hour day for the day and night shifts, and for operators on the evening and split tricks, a seven hour day. Not always, however, is this six day week carried out, for the Bureau found that some 3 per cent of the operators had worked the seven day week from pay roll records for the week ending December 13, 1919. Seven day labor is one which has long been deemed as bad business policy and the telephone company is making every effort to reduce it to a minimum. Aside from the question of fatigue, no operator under any circumstances should be asked to work seven days without any break. Seven day labor is undoubtedly a contributing factor of the labor turnover of the company. It also tends to increase absenteeism and lost time, especially among workers as youthful as telephone operators and where the work is so exacting.

While only a small percentage of the operators were found working in the seven day week, nearly 30 per cent of the operating force worked overtime during the week taken. The amount of overtime varied considerably in the different localities. The largest proportion fell in Brooklyn and the lower Bronx, where 51.65 per cent of the operators worked beyond their scheduled assignment of hours. The highest peak of overtime for the entire state is reached by the number of operators (35.76 per cent) who worked from three to six hours beyond their regular assignment. The next highest peak (35.02 per cent) is reached by those operators who worked from six to nine hours beyond their regular assignment.

The largest amount of overtime existed among the evening operators, in which group 2,381 worked overtime, as against 1,035 day operators and 211 night operators.

Basic Work Day Reduced

The telephone company has gone farther than many other industries in the state in the reduction of its basic work day from nine to eight hours, and in the case of evening and split trick shifts, from nine to seven hours; but the fact that over one-fourth of the operators in New York State work beyond their regular assignment of hours is indicative of a weakness in the labor policy of the company.

In the testimony of the Royal Commission of Toronto, Canada, physicians recommended that the telephone operators should have a work day of seven hours, spread over a nine hour period, and that the time should be divided as follows: two hours work, one-half hour relief; one and a half hours work, one-half hour intermission; two hours work, one-half hour relief; one and a half hours work. They testified further, however, that a seven hour working day would still be too long for telephone operators. The working day should eventually be reduced to six hours actual labor, spread over a period of from eight to eight and a half hours.

This testimony is particularly significant when it is realized that the predominating age for the largest number of new telephone operators is sixteen.

The company definitely desires a certain type of girl—in age, between sixteen and twenty-three, with the excep-

tion for night work operators, where the maximum is thirty-five. The company has in mind the growing policy of the state prohibition of night work, particularly for younger women, and is endeavoring to raise the age of night workers to over twenty-one years. During December, 1919, for instance, of 512 girls who reported for work, 409 were twenty-one years of age or under. So far as experience goes the company prefers girls who are direct from school, without industrial experience. Such girls are more amenable to instruction and discipline and can fit into the company's organization with less effort. Young persons are also preferred by the telephone company because of the greater facility with which they learn to work and acquire dexterity, and because their reactions are much quicker than the reactions of older girls. Yet the years sixteen to twenty-three are those during which the nervous and physical system of a woman is peculiarly sensitive to strain and susceptible to injury. Injury sustained at this time of life is apt to be more far reaching than would be the effects from similar causes in maturer years. The effects upon posterity caused by undermining or weakening the constitutions of these young women gives rise to serious consideration.

In connection with the youth of the operators attention must also be called to the fact that telephone operating does not seem to fit a woman for any other occupation or calling. Additional significance is, therefore, to be given to the fact that the average time spent by operators in the service is from two to three years and that the period of service is usually given at the time when a young woman is best able to learn with advantage the trade or calling which is to put her in the way of acquiring a livelihood during the years of her life.

Wage Policy Unsatisfactory

The wage policy of the telephone company was considered by the Bureau to be unsatisfactory. While the study by the Bureau was being made, three groups of operators had their wage rates increased.

In general, the first increase affected only Greater New York and raised the minimum wage from \$12.00 to \$15.00 and the maximum rate \$1.00. The next increase was made for the operators longer in the service and increased the maximum \$2.00. The third increase was applicable to the other exchanges throughout the state.

Based on a grand total of 10,731 operators—which figure excluded 188 operators whose earnings could not be considered typical, as absence made their earnings below the basic wage—the earnings fell like this: 336 received under \$12.00; 1,983 received between \$12.00 and \$15.00; 2,997 received between \$15.00 and \$18.00; 2,485 received between \$18.00 and \$21.00; and 1,976 received between \$21.00 and \$25.00. After the \$25.00 mark is reached, there is a gradual decline, only 110 persons on the operating force earning as high as \$30.00 per week.

There was in the mind of the Bureau no doubt that the low wage rates and consequent low earning capacity of the operators had much to do during the year 1919 with the company's high labor turnover, resulting in inefficient service. The Bureau believed, however, that the telephone company had not gone as far as it should on wage increases, and that other increases would be necessary if the company hoped to retain a permanent well organized force. The Bureau would not quibble with the telephone company over its minimum wage rate, although the minimum wage rate of telephone operators under the United States Railroad Administration is \$70.00 per month, something over \$16.00 a week. The Bureau believed, however, that the maximum rate was still too low and that the rate of promotion was all too slow.

In comparing the wage rates of the telephone company with those of other industries that require the same qualifications and same standards of efficiency, other employees can reach the maximum wage offered by the telephone company in a much shorter time and know that their wages will be increased in fair proportion to their length of service. Since the biggest asset which the telephone company has is the operator who remains with it longer

than two years, a greater wage incentive should be placed before the girl as an inducement to remain with the company. Furthermore, that a girl should reach her maximum earning capacity, except for the few who become chief operators or supervisors, after she has been with the company six years, which in many instances may be when she has reached the age of twenty-two or twenty-five, is indeed discouraging to any worker and implies poor knowledge of psychology on the part of the telephone company.

It is the opinion of the Bureau of Women in Industry that if promotions were made more rapid and the maximum wage made higher, the telephone company could retain in its service a very much larger percentage of trained operators, thus reducing the cost of training operators and eliminating that large cost which now appears on the books of the company.

A satisfactory system of promotion and wage increases as a reward for efficient service is particularly significant when it is realized that when the study was made, for every three girls who entered the telephone company's service, one dropped out in training and a second before the first year was over, and the third stayed longer than a year. Since the estimated cost of training an operator varies from \$68.00 to \$100.00 per operator, the shorter the length of service of the operator the greater expense to the company. Also, since an operator must be in the service of the company "two years before she can efficiently carry the theoretical load of 230 units per hour," the kind of service which the public receives depends very considerably on the length of service of the operators.

The company cannot altogether control labor turnover, of course, though so far as the question of wages, age at beginning work, opportunities for promotion, fatigue, and sympathetic treatment of employees enters into the problem, the answer lies with them.

In the city of Manhattan, 24.33 per cent of the operators had been with the company six months or less. This is exclusive of students in the training school. What this means, interpreted in terms of service which the public receives from the operators, is that these operators are able to handle efficiently about 75 per cent of the theoretical load of 230 units per hour. While about 24.33 per cent of the operators had been with the company less than six months, the next largest percentage is among the operators who had been with the company over six months and through one year, or 13.68 per cent; and the next largest group had been with the company over one year and through two years, or 12.37 per cent. In other words, slightly over one-half of the operating force in Manhattan had been with the company less than two years. The situation of the telephone company, therefore, resolves itself into the fact that the important element in determining the efficiency of the service, from the point of view of the operator, rests absolutely on the length of service in the occupation.

On the whole, the Bureau of Women in Industry found that the lighting, heating, and ventilation in the telephone exchanges were better than in the average factory, though the ventilation in the operating rooms was still open to some criticism as not being sufficient. The company, it is stated, has gone much farther than the majority of large employers of women in paying particular attention to the physical conditions under which employees work. Seating arrangements, wash rooms, toilets, lockers, rest rooms, and lunch services are commended.

Aside from its value as a report on general conditions in the industry and on the prevalent hours and wages for telephone operators during the year 1919, the study made by the Bureau is significant as suggesting the need for scientific investigation of all industries where intense strain is involved and nervous energy continuously extended. We have not yet more than scratched the surface

in our knowledge of the relation of industrial conditions and health, and only with a basis of such knowledge will we be able to intelligently meet the pressure of modern industrial development.

PENNSYLVANIA INDUSTRIAL PHYSICIANS MEET

Pennsylvania was the first state to form a state chapter, and on December 17, 1920, in Philadelphia, the eleventh meeting was held, with nearly three hundred physicians in attendance. The following program was full of interest and profit.

Program

MORNING SESSION

Address of Welcome, by Honorable Clifford B. Connelley, Commissioner, Pennsylvania Department of Labor and Industry, Harrisburg, Pa.
The Obligation of Industry in Relation to Infant Mortality, by Dr. Ellen C. Potter, Chief, Division of Child Health, Pennsylvania State Department of Health, Harrisburg, Pa.
Discussion: Dr. Edward Martin, Commissioner, Pennsylvania State Department of Health, Harrisburg, Pa.
Our Legislative Program, by Dr. Frederick L. VanSickle, Executive Secretary, Pennsylvania Medical Society, Harrisburg, Pa.
Some Observations on the Treatment of Wounds, by Dr. Hubley R. Owen, Chief Surgeon, Bureau of Police and Fire, Philadelphia, Pa.
Discussion: Dr. W. Estell Lee, Philadelphia, Pa.

AFTERNOON SESSION

Transportation of the Injured, by Dr. R. R. Sayers, Chief Surgeon, Bureau of Mines, Department of the Interior, Washington, D. C. (Illustrated by motion pictures and lantern slides.)
Minimum Physical Standards for the Child Laborer, by Dr. S. Josephine Baker, Chief, Bureau of Child Hygiene, Department of Health, New York, N. Y.
Discussion: Dr. Mary R. Noble, Assistant Chief, Division of Child Health, Pennsylvania State Department of Health, Harrisburg, Pa.
The Rehabilitation of the Industrial Cripple, by S. S. Riddle, Chief, Bureau of Rehabilitation, Pennsylvania Department of Labor and Industry, Harrisburg, Pa. (Illustrated by motion pictures and lantern slides.)
Discussion: Dr. John N. Bassin, Chief Surgeon, New Jersey Rehabilitation Commission, Trenton, N. J.

New Chapters Organized

On November 6, 1920, at Columbus, O., the Ohio State Chapter was formed and organized, with the election of Dr. Don B. Lowe, president; Dr. Sidney McCurdy, vice-president; and Dr. A. J. Lanza, secretary, with thirty charter members.

On January 13, 1921, the New Jersey Chapter was organized with thirty-two charter members.

It is hoped that other states will follow this good example and soon have their chapters.

WHERE ASSOCIATION MEMBERS LIVE

Membership of the American Association of Industrial Physicians and Surgeons will be interested in knowing in what states the members are located:

State—	No. of Mem- bers.	State—	No. of Mem- bers.
Alaska	1	Nebraska	2
Arkansas	2	Nevada	4
Arizona	1	New Hampshire	11
Canada	1	New Jersey	11
California	16	New York	45
Colorado	4	Ohio	64
Connecticut	10	Oregon	2
District of Columbia	4	Pennsylvania	160
Delaware	6	Rhode Island	2
Idaho	2	South Dakota	1
Illinois	91	Tennessee	2
Indiana	11	Texas	1
Iowa	4	Utah	1
Louisiana	2	Virginia	2
Maryland	1	Washington	9
Massachusetts	20	West Virginia	1
Michigan	41	Wisconsin	21
Minnesota	12	Wyoming	2
Missouri	5		

Total membership 565

There are approximately 2,500 physicians in the United States who are specializing in industrial medicine and surgery and many of these should be members of our Association. If you know a physician who is so specializing, why not urge upon him or her to make application?

A postal card to the secretary's office, making the request, will bring you as many membership application blanks as you may need.

Our constitution provides for a Membership Committee and we have a live one, consisting of Dr. C. C. Burlingame, chairman, Dr. Harry E. Mock, and Dr. A. W. Colcord.

They have formulated a questionnaire which is sent to all applicants for membership and which will be of great help to the Committee in determining whether or not the applicant has the necessary qualifications for membership in our Association.

HIGH TEMPERATURES AND HIGH HUMIDITIES

A study as yet inconclusive but highly significant is published in *Public Health Reports* of January 28, 1921, of the "Physiological Effects of High Temperatures and High Humidities in Metal Mines." From the data submitted, the following symptoms were found in workers in still air metal mines, with a wet bulb temperature of 90 degrees F. and under 100 degrees F., and with a relative humidity of 89 per cent or higher: (1) Blood pressure, systolic, and diastolic, fell rapidly. (2) Body temperature rose; in one case it reached 102 degrees F., and this after less than two hours having been spent in the hot, humid air described. (3) Pulse rate increased and seemed more sensitive to exercise than normally. (4) Perspiration was very profuse. (5) Dizziness was a common symptom, and sometimes was marked. (6) Physical weakness or exhaustion was marked in some cases and present in all. (7) Inability to think quickly or accurately was a very common symptom. (8) Nausea was occasionally found. (9) Headache was also occasionally found. (10) Loss of weight was especially marked in men who had been employed under above conditions over a period of years, but occurred even after exposure only a few days. In a still air mine with wet bulb temperature of 85 to 86 degrees and relative humidity of 96 per cent, the symptoms mentioned were not found as long as the subjects remained at rest or took only light exercises. Data should also be obtained as to the effect of hard work in coal mines on blood pressure, bodily temperature, pulse rate, etc.; and similar data should be obtained for air with various temperatures, wet and dry bulb, and still as well as moving air.

HEALTH SUPERVISION AN AID TO INDUSTRY

The National Industrial Conference Board, with headquarters at 10 East Thirty-ninth Street, New York City, has just published the results of physical examinations of industrial workers in thirty-four plants, which go to show that these examinations have increased efficiency, diminished accidents, reduced absence, lowered the labor turnover, eliminated tuberculosis and other contagious diseases, brought about a better adaptation of the worker to the job, and a feeling among the employees that their interests are being intelligently safeguarded. The study includes 410,106 workers—237,183 men and 82,923 women. Little or no objection to the examination was shown on the part of the workers, the largest number of objections being 200 among 62,000 employees. Ten plants employing 155,000 workers had no refusals. Physical examinations were introduced into this group in 1910, but in twenty-three of the thirty-four plants they were not introduced until 1914 or later.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

THE CLEVELAND SURVEY

THE completion of the Cleveland Hospital and Health Survey¹ marks an epoch in the study of health organization in America. We have had many health surveys and some hospital surveys, conducted in various cities and under various conditions; but this is the first time that a comprehensive study has been made of all the complex factors which influence the physical well being of a great community. The survey committee of the Cleveland Hospital Council, under the chairmanship of Malcolm L. McBride, displayed extraordinary vision in outlining a plan which included in its scope, "Development of medical education, both postgraduate and undergraduate; development of nursing education, both general and special; advancement of public health and preventive medicine; and care of the individual sick."

The execution of this project has been as brilliant as the conception which inspired it. Haven Emerson, who directed the work, was ideally fitted for his task by temperament and experience; and the fact that he associated with himself such experts as Michael M. Davis, Jr., Josephine Goldmark, Wade Wright, W. F. Snow, S. Josephine Baker, Donald B. Armstrong, Thomas W. Salmon, Louis I. Dublin, and Robert B. Osgood guaranteed the success of the undertaking. The complete report, in eleven compact volumes, aggregating more than one thousand pages, will occupy a central position on the reference shelves of every student of public health organization.

Volumes I and II of the Survey—dealing, respectively, with General Environment and Sanitation and with Public Health Services and Private Health Agencies,—are modeled very much on the lines of earlier health surveys, although they are on the whole more complete and illuminating than any hitherto conducted. Dr. Emerson's introductory sentence in Volume II,—“Public health organization in the majority of the cities of the United States is more a vision than a reality, a hope of a few rather than a living, growing, democratic function of civil government and private endeavor,”—strikes a true keynote. The primary needs, in Cleveland as elsewhere, are for full time expert service in the positions of Health Commissioner and Bureau Chiefs, and for coordination of private health activities through a strong local Public Health Association.

Part III of the Survey, A Program for Child Health, outlines an admirable plan for the organization of a Central Child Health Council, coordinating public and private agencies, with committees on maternity hospitals, on prenatal care, on infant care, on day nurseries, on children's

institutions, on social service, on nursing, and on dispensaries. Exception may perhaps be taken to the sweeping indorsement of open window ventilation for schoolrooms in this section. Window ventilation combined with gravity exhaust ducts may often prove entirely satisfactory, but window ventilation alone, without structural provision for the removal of the overheated air, and without special and extensive radiation, has been found wholly inadequate to maintain satisfactory atmospheric conditions.

Part IV, on Tuberculosis, shows that Cleveland's accomplishment in this field is far above the average for American cities, although the usual needs for expansion along the lines of more extensive provision for institutional care, increased nursing service, the development of expert medical consultation service and the appointment of a full time chief of the Bureau of Tuberculosis in the Health Department, are clearly indicated.

The removal of discrimination against venereal disease by general hospitals and the establishment of a Bureau of Venereal Disease under the Health Department, are perhaps the most important recommendations in Part V, on Venereal Disease, although emphasis is properly laid throughout this volume upon the diverse educational aspects of this problem.

Part VI, dealing with mental diseases and mental deficiency, reveals inadequacies, perhaps more striking than those indicated in any other section of the survey. Dr. Emerson states that “no more scathing comment upon civil administration could be made than the description of the kind of care provided for the mentally afflicted at City Hospital.” Dr. Salmon's plan for reconstructing the situation involves the creation of a State Commission on Mental Diseases to administer state hospitals and to plan the general campaign, a State Institutional Development Commission to formulate a ten-year program of institutional development, radical changes in legal procedure with regard to mental cases, extensive increases in institutional clinic and social service, the coordination of private agencies through a strong committee on Mental Hygiene, and many other steps which cannot be summarized in brief. This volume is one of the most brilliant contributions of the Cleveland Survey and presents perhaps the broadest and best program for mental hygiene which has yet been put in printed form.

Volume VII, on industrial medical service, women and industry, and children and industry, opens up a new vista in the field of health surveys. It reveals the chaotic condition of industrial medicine and industrial nursing, the need for standardization and for expansion along the lines of cooperative dispensaries, and of the general practice of routine physical examination. It indicates also the

1. Report to be obtained from the Cleveland Hospital Council, 308 Anisfield Bldg., Cleveland, O.

need for improvement in the legislation designed to safeguard women and children, and for better enforcement of the laws which now exist.

Part VIII, which deals with education and practice in medicine, dentistry, and pharmacy, presents a program for the reorganization of the medical school of Western Reserve University, advocates much needed steps for the regulation of quacks and nostrums, and urges the development of a training school for dental hygienists.

Part IX, on nursing, is another volume of the survey which breaks practically new ground, in its recognition of the fact that radical changes in educational standards are essential if the type of nurses is to be found necessary to play an effective part in the modern public health campaign. Miss Goldmark brings forcible evidence of the haphazard conditions which exist in many training schools and recommends the organization of a university school of nursing, with definite improvements in existing schools, which shall tend to develop them as real educational institutions with sound preliminary theoretical instruction and ward work, correlated with theory, and in kind and amount needed by the pupil for her education, rather than in the kind and amount dictated by the needs of the hospital for nursing service. The working out of a course along such lines should make it possible to diminish the usual three year period of training by at least eight months; but high school graduation should be required for entrance.

Volume X, on hospitals and dispensaries, gives a particularly exhaustive and illuminating program for the development of facilities for the care of the sick, with detailed recommendations in regard to hospital and dispensary organization and financing. It deals with such problems as those presented by the convalescent and the chronic case, which are too often omitted from consideration. Finally, Part XI discusses the methodology of the survey, with a suggestive bibliography of surveys and an index to the entire report.

It seems almost futile to attempt in two pages to review the salient points in a thousand pages of compact material. Yet it seems essential to call the attention of all public health workers to this mine of information which Dr. Emerson and his colleagues have prepared, and to express the debt that we all feel for the unique service which they have rendered to the cause of public health.

EDITOR.

AMERICAN JOURNAL OF HYGIENE

THE first issue of what constitutes a new and unquestionably authoritative medium for reports of research along the lines of public health and hygiene appears in the *American Journal of Hygiene*, of January, 1921. The *Journal* is edited by William H. Welch of the School of Hygiene and Public Health of the Johns Hopkins University, supported by an editorial staff representative of the leading institutions of research in the United States. It will be devoted exclusively to the publication of papers representing the results of original investigations in the domain of hygiene "using the term in its broadest sense to cover all applications of the mathematical, physical, chemical, medical, and biological science to the problems of personal and public hygiene." The serial publication is to be supplemented by monographic reports from time to time on the results of the more comprehensive studies. The first issue contains articles as follows: "The Development of the Japanese Blood-Fluke, *Schistosoma japonicum* Katsurada, in Its Final Host," by William W. Cort; "The Action of Light on the Leucocyte Count," by Janet

Howell Clark; "An Experimental Study of the Intracranial Parasitism of the Living Fluke, *Paragonimus westermanii*," by Sadamu Yokogawa and Susumu Suyemori; "On the Relationship of Infection by Hookworm to the Incidence of Morbidity and Mortality in 22,842 Men of the United States Army at Camp Bowie, Texas, from October, 1917, to April, 1918," by Charles A. Kofoed and John P. Tucker; and "Recent Experimental Studies on Yellow Fever," by Hideyo Noguchi.

NOTED HEALTH WORKER PASSES

THE history of public health in this country extends over only the last forty years. During this entire period no one man has had a greater share in its development than Professor William T. Sedgwick, who died in Boston on January 25. He graduated from Yale in 1877 and received his degree as Doctor of Philosophy from Johns Hopkins in 1881. In 1883 he went to the Massachusetts Institute of Technology, where he served successively as assistant and associate professor, professor, and head of the Department of Biology and Public Health.

WILLIAM T. SEDGWICK, 1855-1921.

He saw the Institute grow from its one building in Copley Square in Boston to the great white college which now graces the bank of the Charles River in Cambridge. He was a friend and biographer of the first president, William Barton Rogers. Many famous men have been pupils of Professor Sedgwick; who does not recognize the names of C.-E. A. Winslow, S. C. Prescott, E. B. Phelps, S. M. Gunn, D. B. Armstrong, W. H. Brown, W. W. Peter, and C. E. Turner, to mention only a few? Professor Sedgwick was also chairman of the Administrative Board of the Harvard-Technology School for Health Officers.

In 1888 Dr. Sedgwick was appointed biologist to the newly established State Board of Health of Massachusetts, a position he held for eight years. His work in investigating the famous typhoid epidemics in Lawrence and Lowell made him the leading epidemiologist of the country. In 1902 he published his "Principles of Sanitary Science and the Public Health," which was the classic on this subject. In spite of the encroachments of time, this book will never be out of date in many respects. His other works include "The Human Mechanism" (with Dr. Hough), a standard textbook on physiology; "General

Biology" (with Dr. Wilson), and "A Short History of Science" (with Professor Tyler), besides many articles in scientific magazines.

To enumerate all the positions of trust held by Professor Sedgwick and the well deserved honors he had attained would require many pages. He received the honorary degree of Doctor of Science from Yale in 1909 and the Doctor of Laws from the University of Cincinnati in 1920. He had been on the advisory board of the United States Hygienic Laboratory since 1902 and was an assistant surgeon general (reserve) of the United States Public Health Service. He was also a member of the International Health Board of the Rockefeller Foundation and of the Public Health Council of the State of Massachusetts. He had served as president of the New England Water Works Association, the Society of American Bacteriologists, the American Society of Naturalists, and the

American Public Health Association. He was a Fellow of the American Academy of Arts and Sciences, Fellow of the American Association for the Advancement of Science, Fellow of the Royal Sanitary Institute, Curator of the Lowell Institute, and a trustee of many institutions. A year ago he went to England as exchange professor and delivered lectures at Cambridge and the University of Leeds. He was interested in many civic movements and always stood for the best things in government.

The highest honor possessed by Professor Sedgwick, however, was the universal love and respect of his fellowmen. His personality inspired his pupils and associates; his encouragement made a man want to achieve; his friendship was something to be proud of. As the years come and pass in the corridor of time, this esteem and love shall endure to memory's end. What greater glory can man have than this?

JAMES A. TOBEY.

THE CONTROL OF SMALLPOX

By JOHN N. FORCE, M.D., GR.P.H., SPECIAL EXPERT, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

THAT smallpox is extremely prevalent in the United States is evident from the following table of cases reported to the United States Public Health Service from twenty states during the years 1915-1920.

As an example of the rapidity of increase may be cited

which slowly spread over the country. On the Atlantic Coast this disease was in such close relation with the Spanish-American War that it received the name "Cuban Itch," while on the Pacific Coast its appearance, coinciding with the later operations in the Philippines, suggested

the cases reported to the California State Board of Health during the years 1916-1920. In 1916 there were 248 cases reported; in 1917, 329 cases; in 1918, 1,100 cases; in 1919, 2,053 cases; and in 1920, 4,486 cases, the last figure representing an eighteen-fold increase of the disease in five years.

Studies of the age distribution of the California cases for the years 1916, 1918, and 1919 show that in 1916 half of the cases occurred before age 22; in 1918, half before age 20; and in 1919, half before age 17. In 1916 the case rate for children per thousand of total population was only slightly greater than for adults; in 1919 the case rate for children was twice that of adults. These statistics show not only a remarkable increase in smallpox during the last few years, but that this increase has been principally among the children. This general prevalence, as well as the local increase and changes in age distribution, is attributable to two causes—errors in diagnosis, and neglect of juvenile vaccination. Conversely, the control of smallpox in a community depends on accurate diagnosis and supervision of the disease, associated with prompt and efficient vaccination.

In 1896 there appeared in Florida a mild form of smallpox, apparently not of the variety described in textbooks, the name "Manila Itch." The mistake in diagnosing this mild smallpox, either as a new disease of tropical etiology,

or as chickenpox, has allowed many epidemics to attain formidable proportions before the disease took on sufficient textbook characteristics to permit of a true diagnosis.

The following routine practice in the diagnosis of smallpox is not original, but may be found of value by health officials encountering an epidemic characterized by these doubtful cases.

(1) *Visits*.—A few years ago it was considered sufficient for representatives of health departments to see adult cases notified as chickenpox for the purpose of confirming the diagnosis. At that time the child population was fairly well vaccinated, but many previously vaccinated adults were no longer immune. Chickenpox was primarily a children's disease, and a case occurring in an adult was always suspected of being smallpox.

At present, as has been shown, smallpox is rapidly tending to become a children's disease, and alert health officials should confirm the diagnosis in every case notified as chickenpox.

The person making the visit should check dates of exposure, onset of symptoms, beginning of eruption, etc. A supply of investigation forms should be carried. In planning these forms care should be taken not to overload them with a mass of detail, and, on the other hand, to omit nothing contributory to the diagnosis. For example,

"Sanitary condition of premises" conveys no information in an investigation of smallpox, while "History of chickenpox" is of great significance. Some investigation cards are provided with four outlines of the human figure—front, back, left side, right side—which are convenient for rapidly shading in the distribution of the eruption.

(2) *History*.—The date and character of onset should be ascertained, including history of chill, fever, backache, headache, and vomiting. The duration of this pre-eruptive stage is of importance, being usually about three days. Inquiry should be made as to the date of eruption and the region where first seen.

The investigator should obtain the *history of exposure* to any eruptive fever; smallpox cases usually have an incubation period of twelve days, perhaps slightly longer in the mild type. As the eruption appears with great regularity on the third day of the disease, about two weeks before this date may be safely taken as the time of exposure. If the patient was outside the jurisdiction of the local health officer at the time of exposure, his whereabouts should be carefully ascertained in order that the health officer of the jurisdiction in which the exposure took place may be notified and perhaps assisted in the discovery of an unsuspected focus of smallpox.

A note should be made of the condition of the patient; smallpox patients in the early eruptive stages are fairly comfortable as compared with their pre-eruptive state. The history of chickenpox and the vaccination history should be obtained. From the statements of the patient a history will be secured about as follows:

Patient, colored, 25, laborer; history taken Wednesday. Two weeks ago, Sunday, went to see cousin sick with chickenpox; patient had had chickenpox, so was not afraid. Last Friday, while at work, had a chill and began to have severe headache and pain in the back. Came home, took salts and went to bed. Saturday no better, so called a doctor, who pronounced it "grip" and left medicine. Saturday night ate strawberries, which he vomited. Sunday not much change, but awoke Monday morning feeling "fine" and decided to go to work. While shaving noticed "pimples" on forehead and around mouth. Patient feels fairly well, except for slight itching. He was first vaccinated two years ago in the army, but has only a pigmented spot, with no pits.

Had this been a case of chickenpox the history would have been about as follows:

Assuming the same exposure, the patient would have noticed a chilliness and perhaps headache and general malaise Sunday afternoon. On Monday morning he would have awakened feeling worse and would have discovered the eruption. Fever would accompany the eruption and the period of remission so characteristic of the early eruptive stage of smallpox would be absent.

(3) *Distribution of eruption*.—Having obtained the history, the investigator should require the patient to strip to the waist. No satisfactory estimate of the distribution of the eruption can be made from inspection of the hands and face. The investigator should not consider single lesions or groups of lesions at this time, but should stand far enough away from the patient to form an estimate of the regional distribution of the eruption as a whole. If the patient is required to cross the arms, place the hands on opposite shoulders, and flex the head on the chest, the regions most invaded by the smallpox eruption will be brought together, i. e., the face and forearms. If the patient then opens wide the arms, holding them out from the body while throwing back the head to expose the chest and neck, the regions least invaded by smallpox will be brought to view, i. e., the chest, neck, and upper arms. It will be noted that the axilla is practically free from the eruption. The contrast between invaded and comparatively free surfaces presented by the above pro-

cedure is very striking. Chickenpox eruptions, on the other hand, invade the chest, neck, axilla, and upper arm, the lesions being fewer on the forearm than on the upper arm. *Either* eruption may appear on the palms and soles. Smallpox may appear a day or so later on the hands than on the face, consequently an attempt to make a diagnosis without stripping the patient may result in disaster.

(4) *Character of the eruption*.—The textbook description of the smallpox lesion is familiar to all. Much stress is laid on the "shotty" feel of smallpox contrasted with the "blister-like" chickenpox eruption, and the successive crops of chickenpox lesions are contrasted with the single stage of development shown by the lesions of smallpox in any region of the body. Much has also been written about umbilicated and multilocular lesions in smallpox. In the presence of a mild type of smallpox, or one influenced by previous vaccination, many of these distinctions either disappear or become hard to discern. Usually in chickenpox, especially in the skin folds, e. g., on the lower abdomen, a few large oval vesicles may be seen. These furnish a sharp contrast to the round lesions of smallpox. The presence or absence of umbilication is not a safe guide. It may be necessary to depend on the history of the case and the distribution of the lesions rather than on the differentiation of the lesions themselves. With a total of twenty lesions on the body surface, not much can be discovered about successive crops, but if fifteen of these lesions are on the forearm and face, and they appeared after a two days' attack of "grip," there is little doubt as to the diagnosis.

(5) *Tracing contacts*.—After being satisfied as to the diagnosis of smallpox, the next duty of the investigator is to ascertain the names and addresses of all persons with whom the patient has been in contact during the pre-eruptive and early eruptive stages. The contacts during the early eruptive stage may be hard to locate because, in many instances, the patient returns to school or work when the pre-eruptive symptoms have passed.

The contacts should be followed up, vaccinated, and kept under observation for from two to ten days, until evidence of immunity is secured, as described below in the section on immunity. Contacts refusing vaccination should be quarantined for a period of two weeks dating from the last exposure.

(6) *Disposal of the patient*.—A smallpox patient isolated from contact with all but the recently immunized is no more a menace to the public than a yellow fever patient in a well screened bed. The question of removal to a contagious disease hospital is one of expediency. The contagious disease hospital is more of an economic ally of the afflicted family than a protection to the public health, as was formerly believed before the part played by carriers and missed cases was so well understood. The necessity for removal is of course always indicated where family quarters are crowded or the patient is an inmate of a hotel, boarding house, or club. Nothing is gained by the quarantine of immunes; in fact, the tendency to strict family quarantine in smallpox is responsible for the concealment of many mild cases.

It has been stated that 4,486 cases of smallpox were reported to the California State Board of Health in 1920. Definite histories as to vaccination or lack thereof were secured from 4,226 of these cases. Only 1 per cent had been vaccinated during the five years immediately preceding the attack of smallpox; 7 per cent had been vaccinated more than five years before; while 92 per cent had never been vaccinated.

It is easy to secure testimony that vaccination prevents smallpox, but hard to overcome a disposition on the part

of the public to regard variola and vaccinia as two evils, both to be avoided if possible, and when avoidance is no longer possible, to determine which is the lesser.

Formerly the fear of smallpox caused people to regard vaccinia as the lesser evil, but there seems to be little fear of the present mild smallpox and much fear of vaccinia, arising from family experiences with vaccination performed by ancient methods, unfortunately still too prevalent. It is the duty of public health officers, physicians, and public health nurses to combat the reasonable objections to vaccination by demonstration of the harmlessness of the modern procedure, some details of which will now be considered:

(1) *Smallpox vaccine*.—Smallpox vaccine consists of a suspension in aqueous solution of glycerin of living smallpox organisms, modified by having been grown on calves. The result of this propagation on the calf has rendered the organism incapable of reproducing clinical smallpox. Only by direct inoculation of the vaccine on the derma can the characteristic vaccinia lesion be produced, through the multiplication of the inoculated organism to form a colony whose growth stimulates antibody formation in the vaccinated person. Every detail of the manufacture of smallpox vaccine is safeguarded through inspection and regulation by officers of the United States Public Health Service. The purity of the product is beyond question, but its potency is largely influenced by the care it receives after leaving the producing establishment. Smallpox vaccine withstands the lowest temperatures experimentally produced, but the living organisms are destroyed in a comparatively short time at body temperature. Public confidence in the efficacy of vaccination is not enhanced if packages of vaccine are left near a steam pipe in a mail car, placed on a shelf in a jobber's warehouse, thrust into a drawer in the retail pharmacy, and finally carried in a bag on the floor of the physician's machine. Persons naturally immune to vaccinia are extremely rare, in fact much rarer than is generally supposed. The vaccinator should bear this in mind; if vaccinia is not uniformly produced in previously unvaccinated subjects, the vaccine is probably at fault, and the vaccination should be repeated with a product which has been kept on ice as much as possible since leaving the producing establishment. Health officials vaccinating during epidemics should provide means whereby the vaccine taken into the field may be iced up to the moment of use.

(2) *Technic of vaccination*.—The vaccine colony grows on the derma, under the unbroken epidermis. It is possible to vaccinate intracutaneously, using the technic of the Schick test. It is, however, easier and much safer to break the epidermis and bring the vaccine in contact with the derma. The epidermis may be broken by the single scratch of a needle, or better, by removing a tiny portion of epidermis by the rotation of a vaccination chisel, held perpendicularly, leaving exposed a circle of derma 3 mm. ($\frac{1}{8}$ inch) in diameter. Three scarifications, at least 5 cm. (2 inches) apart, should insure against failure of technic, and will result in scars each 10 mm. ($\frac{3}{8}$ inch) in diameter, much less disfiguring than the scar produced by necrosis, the result of cross-scarification. The vaccine must grow in unbroken skin, so nothing is gained by a single cross-hatched denuded area which could not have been secured by dividing this area into several smaller portions. Some vaccinators advise scarification through the drop of vaccine, but it is harder to observe the character of the scarification when this is done. The vaccine should be dropped on the scarified area and worked in lightly with the flat of the vaccination chisel, or a sterile toothpick. The skin may be cleansed

with alcohol previous to vaccination, but the vaccination chisel should be sterilized by dipping in alcohol and burning off. It is best to vaccinate on the arm; no vaccination should be done on the leg. It is not necessary for the vaccinated area to be dry before rolling down the sleeve. If the single needle scratch or the vaccinating chisel is used, sealing of the trauma is almost immediate and the vesicles resulting from the small insertions are not readily broken. There is, therefore, no need of a dressing for protection, and, indeed, the dangers resulting from dressings outweigh any advantages. Dressings furnish excellent incubator facilities for pyogenic organisms. Vaccination shields are especially dangerous and should never be employed. Not only do they fail to give protection against trauma, but any constriction over or near the vaccinated area causes edema and maceration. The bare arm should not be exposed to direct sunlight for a few hours after vaccination.

(3) *Immunity*.—The object of vaccination is to secure immunity against smallpox. This immunity is verified not by large, disfiguring scars, but by careful observation of the reactions following vaccination. Vaccination and revaccination should be continued until evidence of immunity is secured. No vaccinator is justified in assuming that a subject is immune because several attempts to vaccinate have appeared unsuccessful when observed at the end of a week, but much time and vaccine are wasted in the revaccination of immune persons.

Immunity is established as soon as antibodies are formed, which, in the case of a previously unvaccinated person, is usually on the tenth day following vaccination. This antibody formation may be accelerated, depending on the degree of sensitization of the subject through previous vaccination. Whenever antibody formation reaches a certain height the growth of the vaccine organism is arrested. Thus, a group of persons with varying degrees of immunity before the vaccination, will exhibit at the time of this arrest lesions ranging from primary vaccinia characterized by an 11 mm. vesicle surrounded by a 35 mm. areola at its height on the tenth day; through the secondary vaccinia (vaccinoid) with a 6 mm. vesicle surrounded by a 20 mm. areola on the fifth day; to, finally, most significant of all, the 7 mm. areola, with or without a papule on the second day, which marks the reaction of highest immunity.

If vaccinations are not observed until the seventh day, this immediate reaction of immunity will have disappeared and the vaccinator will be in doubt as to whether the "unsuccessful" vaccination is due to immunity or to impotent vaccine. A fifth day observation is better than a seventh day, for a slight brownish pigment may mark the site of the receding reaction of immunity. Any doubtful result should indicate the necessity for revaccination and observation at the end of forty-eight hours.

A person submitting to vaccination is entitled to a full measure of protection. Assurance of this can only be afforded by the observation of one of the manifestations of vaccinia described above.

The control of smallpox depends on diagnosis and vaccination. It is important that certain mild types of smallpox now prevalent in the country should be recognized, and not confused with "grip" or chickenpox. Vaccination of contacts is far more important in checking the spread of smallpox than quarantine and disinfection. Vaccination depends for its success on a supply of fresh, cold virus; the use of small multiple scarifications in preference to a single, large cross-scarification; and, finally, the recognition of the difference between a failure due to impotent vaccine and the reaction of immunity.

DIETARY HYGIENE AS TAUGHT BY MUSEUM METHODS*

BY MARY GREIG, DEPARTMENT OF PUBLIC HEALTH, AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK CITY

IT IS not possible or profitable to try to remember the individual values of each food. Therefore, we group foods according to the general type of nutritive need which they supply. No one group of foods furnishes a complete diet because each lacks some essential thing. Whenever it is necessary to economize in the diet, we must rely chiefly upon the grain products for nourishment since they give us energy at a low cost and a cheap, although not completely adequate, supply of proteins. These foods, however, lack calcium and are deficient in vitamins. Therefore they must be supplemented by foods which supply these essentials.

Milk is the food richest in calcium and it supplies also the fat-soluble vitamins and the indispensable animal proteins. Vegetables are rich in mineral salts; they promote a healthy condition of the intestines; and some vegetables are important sources of vitamins.

These three food groups—grain products, milk, and vegetables—when taken together, form an excellent foundation diet which can be further supplemented by other foods.

Meat, fresh fish, poultry, eggs, and most fresh fruits must play a minor part in a low priced diet. They are good foods, but they supply no nutritional needs which cannot be met more cheaply in other foods.

Table III of the school exhibit sums up the essential facts in regard to the special values of various classes of foods. It will be noted that:

*Part I of this article appeared in the February issue.

The cheapest sources of energy are the grain products and legumes, sugars, and fats. The grain products are deficient in certain kinds of protein and in calcium; sugars and fats contain neither proteins nor salts.

The most complete proteins are supplied by meats, milk, and eggs. Calcium is best supplied by milk and green vegetables; iron by meat, eggs, vegetables, and fruits. Milk, butter, eggs, and green vegetables are the best sources of the fat-soluble vitamins. The water-soluble vitamin B is found in most foods though lacking in sugar and butter and not abundant in root-vegetables and highly milled grain products. The antiscorvy vitamin is best obtained from oranges and tomatoes, though present in most fresh foods.

Foods are made up of the following (1) Constituents which supply no energy: (a) water; (b) refuse and (c) mineral salts; (2) constituents which supply energy: (d) carbohydrates—sugars and starches; (e) proteins—nitrogen containing material; and (f) fats.

The mineral salts and water are valuable as building materials. The last three constituents listed above contribute energy as well as building materials. Carbohydrates and proteins furnish the same amount of energy per ounce or gram (113 calories per ounce or 4 calories per gram); but fat furnishes more than twice as much energy as either (255 calories per ounce or 9 calories per gram).

Goods vary enormously in the relative amounts of these constituents. This may be illustrated by setting up the

TABLE III—SPECIAL VALUES OF VARIOUS FOODS

	Energy	Protein	Mineral Salts	Fat Soluble A	Water Soluble B	Anti-Scurvy C
Grain products and dried beans and peas.....	Cheapest source.	Cheap source, but deficient in certain necessary kinds of protein.	Good source of certain salts, but lacking in calcium.	Variable.	Present except in highly milled grains.	Lacking.
Meats	Costly source but depends largely on cut.	Contain proteins of good quality.	Source of iron but lacking in calcium.	Abundant.	Present.	Very low content.
Root vegetables.....	Fairly cheap source.	Contain certain proteins but inadequate as sole source.	Good source.	Variable.	Not abundant.	Present usually abundant.
Sugars	Very cheap source.	Lack proteins.	Lack salts.	None.	None.	None.
Fruits	Fresh fruits expensive source. Dried fruits fairly cheap source.	Poor source.	Fresh fruits costly source; dried fruits cheap source.	Unknown.	Present.	Abundant, especially in orange, lemon and tomato.
Nuts	Cheap source.	Fairly cheap proteins but inadequate as sole source.	Good source.	Unknown.	Unknown.	Lacking.
Milk	Fairly cheap source.	Good quality proteins.	Best source.	Abundant (milk is the best source of this vitamin).	Present.	Present.
Leaf vegetables.....	Very little energy value.	Fairly good source.	Valuable source, especially for calcium and iron.	Abundant.	Present.	Present—usually abundant.
Butter	Cheap source.	Lacking proteins.	Poor source.	Abundant.	Lacking.	Lacking.
Eggs	Expensive source.	Expensive source, but contain proteins of excellent quality.	Rich in mineral salts. Lower than milk in calcium.	Abundant.	Present.	Unknown.

TABLE IV. THE CHILD'S DAILY DIET
Examples of Foods That Make Up a Healthful Breakfast

Necessary types of food	Calories to be supplied by each type	Amounts of food that supply the necessary number of calories
Fruit	50-100	Apples $\frac{1}{2}$ to 1 or bananas $\frac{1}{2}$ to 1 or oranges $\frac{3}{4}$ to $1\frac{1}{2}$ or Malaga grapes..... 10 to 20
Cereal	100-150	Rolled oats..... 1 to $1\frac{1}{2}$ c. cooked or cornmeal or flaked wheat..... $\frac{2}{3}$ to 1 c. or cornflakes or puffed rice..... $1\frac{1}{2}$ to 2 c. or shredded wheat..... 1 to $1\frac{1}{2}$ biscuits
Bread	50-100	Whole wheat 1 to 2 slices or white bread.....
Butter or butterine.....	50-100	Butter or butterine..... $\frac{1}{2}$ to 1 Tbs.
Milk, or cocoa made with milk.....	100-150	Milk $\frac{2}{3}$ to 1 c. or cocoa made with milk $\frac{3}{5}$ to 1 c.
Total	400-600	

TABLE V.—THE CHILD'S DAILY DIET.
Examples of Foods That Make Up a Healthful Dinner

Necessary types of food	Calories to be supplied by each type	Amounts of food that supply the necessary number of calories
Meat, fish or eggs.....	75-300	Lamb stew..... 1 to 3 small pieces, $\frac{1}{2}$ oz. or eggs 1 egg 70 calories or chicken 1 to 3 slices (slice 2 x 4 x $\frac{1}{4}$ inches)
Potatoes, rice, macaroni, etc. ...	100-200	White potato..... 1 to 2 medium or sweet potato..... 1 to 2 small or boiled rice..... $\frac{3}{4}$ to $1\frac{1}{2}$ cups
Fresh vegetables	25- 50	Spinach $\frac{1}{2}$ to 1 cup, cooked or carrots 1 to 3 medium or turnips $\frac{1}{2}$ to 1 c. sliced or tomatoes $\frac{1}{2}$ to 1, medium or cauliflower $\frac{1}{8}$ to $\frac{1}{4}$ head
Milk	100-150	Milk $\frac{2}{3}$ to 1 c.
Bread	100-	White bread 2 slices
Butter	100-	Butter 1 Tbs.
Pudding or similar dish.....	200-300	Rice pudding..... or apple tapioca..... or cornstarch blanc mange or Brown Betty pudding or ice cream..... } $\frac{1}{2}$ to $\frac{3}{4}$ cup
Total	700-1,200	

Key: C. cup; Tb. tablespoon; t. teaspoon.

TABLE VI.—THE CHILD'S DAILY DIET
Examples of Foods That Make Up a Healthful Supper or Lunch

Necessary types of food	Calories to be supplied by each type	Amounts of food that supply the necessary number of calories
Cream soup or similar dish.....	200-300	Cream of tomato..... or celery or spinach..... or asparagus or pea..... or split pea or bean soup or mashed or creamed potatoes or boiled macaroni..... } 1 to $1\frac{1}{2}$ cups
Bread	50-100	White or whole wheat..... 1 to 2 slices
Butter or butterine.....	50-100	Butter or butterine..... $\frac{1}{2}$ to 1 Tb.
Stewed fruit.....	100-200	Stewed prunes..... about 2 to 5 prunes and 2 to 4 Tbs. juice or apple sauce..... $\frac{1}{2}$ to 1 cup or stewed apricots..... $\frac{1}{4}$ to $\frac{1}{2}$ cup
Cake	50-100	Plain cookies, 2 $\frac{1}{4}$ in. diam. 1 to 2 or lady fingers..... 1 to 3 or 1-egg cake, 2-in. cube $\frac{1}{2}$ to 1 cube
Milk, or cocoa made with milk....	100-	Milk $\frac{2}{3}$ cup or cocoa made with milk $\frac{3}{5}$ cup
Total	400-800	

Key: C. cup; Tb. tablespoon; t. teaspoon.

colored blocks which show the composition of seven common foods and comparing them for any one constituent; for instance, notice the difference in water content. Supplement this demonstration by data for other foods from Bulletin 28 already referred to.

Those foods that have large amounts of either refuse or water in them will not usually furnish much energy per pound. Those foods that contain large amounts of fats will be the foods highest in energy. For example, peanuts are about 25 per cent refuse (shells) and one would expect them to be low in energy value; but, on the other hand, they contain very little water, only 7 per cent, and one-third of their substance consists of fat. These two constituents counterbalance the shells which constitute refuse and as a result very few foods give us as much energy per pound (1,900 calories).

The Daily Diet

Perhaps the most convenient manner of regulating our food properly is by means of the food plan or dietary—a rough outline to which all meals should conform.

Many food plans have been issued. A very good one is the following which is adapted from one issued by the Nutrition Division of the Department of Agriculture.

A daily diet plan for the school child from 10 to 13 years of age prepared by the Department of Health of the American Museum of Natural History is presented in Tables IV, V, and VI.

The fundamental essentials of dietary hygiene have been put in a still simpler form, designed especially to appeal to the child himself in Table IX and Fig. V.

Similar diets for younger children and infants may be found in Professor Rose's "Feeding the Family."

An example of the three meals indicated in Tables IV, V, and VI can be made up by combining the models included in the food exhibit as follows:

DAILY DIET FOR ADULT MAN

	Moderate priced	Cheap
Vegetables and fruits.....	2½ lbs.	1½ lbs.
Milk	1 pt.	1 pt.
Meat, eggs, cheese, etc.....	12 oz.*	4 oz.*
Cereals	8 oz.	16 oz.
Sugar and syrups.....	3 oz.	1½ oz.
Fats	3 oz.	1½ oz.
Water	about 1 qt.	about 1 qt.

*Use 2 ounces less of these for each half pint of milk used.

TABLE VIII.—FOODS THE CHILD NEEDS EVERY DAY

Milk	One quart a day.
Cereals	These foods should furnish about ¼ to ½ of the daily supply of energy. The following amounts would give this: 1 to 2 cups of cooked cereal, 6 slices of bread, and ½ cup of cereal pudding.
Fresh vegetables.....	One cupful at least of cooked fresh vegetables.
Fat	About 3 to 4 tablespoons. If a quart of milk is used, some other fat may be substituted for butter.
Fruits	Once a day at least. If fresh fruits are expensive use stewed dried fruits. Fruits should be cooked for the evening meal and at all meals for children under six.
Water	4 or 5 glasses.

TABLE VII.—THE CHILD'S DAILY DIET
Calorie, Protein, and Salts Value of Typical Foods

Breakfast	Amounts	Calories	Protein grams	Calcium grams	Phosphorus grams	Iron grams	Cost May, 1920
Oatmeal	1 c. cooked	100	4.20	.017	.099	.0010	.004
Toast	2 slices	100	3.50	.011	.035	.0003	.009
Butter or butterine.....	1 Tb.	100	.13	.002	.002013
Cocoa	3/5 c.	100	2.70	.080	.08002
Baked apple with sugar.....	1 apple	100	.48	.009	.015	.0004	.05
Milk	2/3 c.	100	4.75	.174	.134	.0003	.02
		600	15.76	.293	.365	.0020	\$.096
Dinner							
Lamb (stew).....	1½ oz.	100	6.33	.003	.060	.0010	\$.017
Potato	1 medium	100	2.65	.016	.069	.0016	.019
Spinach	1 c. cooked	50	4.39	.140	.112	.0075	.081
Whole wheat bread.....	2 slices	100	3.95	.020	.071	.0006	.009
Butter or butterine.....	1 Tb.	100	.13	.002	.002013
Milk	1 c.	150	7.10	.260	.200030
Rice pudding.....	1½ c.	200	5.80	.160	.140030
		800	30.02	.601	.684	.0107	\$.199
Supper or Lunch							
Cream of tomato soup.....	1 c.	200	5.40	.159	.120	\$.647
Bread	2 slices	100	3.50	.011	.035	.0093	.009
Butter or butterine.....	1½ Tb.	50	.06	.001	.001006
Stewed prunes.....	5, and 4 Tbs. sauce	200	1.40	.040	.070	.0020	.040
Milk	1 c.	150	7.10	.260	.200030
Cookies	2	100	1.20	.462	.020010
		800	18.66	.446	.446	.0023	\$.142
Totals		2,200	64.44	1.356	1.495	.015	\$.437
Needs—10-13 years		1,800 to 2,500	45 to 62	.41 to .58	.86 to 1.2	.009 to .013

PERCENTAGE COMPOSITION OF CERTAIN COMMON FOODS

	Refuse	Water	Protein	Fat	Carbohydrate	Salts
Sugar	100 (12)
Butter	11 (1.3)	1 (.1)	85 (10.2)	3 (.4)
Beef	8.1 (1)	64.4 (7.7)	19.5 (2.4)	7.3 (.8)	1 (.1)
Bread	35.6 (4.3)	9.3 (1.1)	1.2 (.1)	52.7 (6.4)	1.2 (.1)
Apple	25. (3)	63 (7.7)	.3 (.04)	.3 (.04)	10.8 (1.3)	.3 (.4)
Milk	87 (10.5)	3.3 (.4)	4 (.4)	5 (.6)	.7 (.1)
Spinach	92.3 (11.1)	2.1 (.3)	.3 (.04)	3.2 (.4)	2.1 (.2)
		Brown Green	Red	Yellow	Blue	Black

Note:—The figures in parenthesis indicate the height in inches of the blocks used when calculated on a basis of 1 foot = 100%. The colors are those used in the museum exhibit.

Food Budget Apportioned

A very useful way to find out whether the diet is well-balanced is to compare the amount of money spent for the different groups of foods.

The average person of limited income spends nearly half of his income for his food. The annual expenditure for this purpose in the United States runs well over seven billion dollars annually.

In New York City fifty cents a day is the lowest sum which will enable an adult to buy adequate nourishment in the form of raw food.

The proper way to apportion the money spent for food when living on a medium income is cited from Prof. H. C. Sherman in the second column of the Food Budget Table. The first column shows the manner in which the average American family, as represented in 208 dietary studies, actually spends its food money. The contrast between the two sets of figures indicates the changes we ought to make in our diet. The third column* shows the proper apportionment of money in an adequate family diet for 1920 on an income slightly above the minimum, as planned by the Department of Public Health of the Museum. In a minimum diet the amount of money spent for cereals and breads may be one-fourth of the whole amount spent for food, and eggs will play a smaller part than would be the case if more money could be spent for food.

For the reason that the prices of sugar and fresh vegetables and fruits went up disproportionately in 1920, the figures for these items are higher in the last column than they would be in normal times. The adjustment was made by spending less money for meat and fish.

The main essentials of an adequate and economic diet are presented on this budgetary basis in the exhibit on Food Hygiene installed in permanent form in the American Museum of Natural History by the following diet list for a family of five for a week:

The main essentials in the program for securing a more

adequate diet at a minimum cost may be stated in a single sentence. Restrict expenditures for meat, fish, poultry, sugar, and fats, and spend more money upon vegetables and fruits—and, particularly—upon milk.

FOOD BUDGETS

Food groups	How the Food Budget is spent (Sherman) Per cent	How the Food Budget should be spent (Sherman) Per cent	How it should be spent on a low income in 1920 A. M. N. H. Per cent
Meat, poultry, and fish	31.	10-15	8.61
Eggs	5.7	5-7	2.36
Milk	9.6	23-30	22.08
Cheese	1.	2-3	3.39
Fats	8.6	10-12	9.93
Breads and cereals	17.	12-15	15.29
Sugars and syrups	4.5	about 3	5.67
Vegetables and fruits	15.	15-18	20.75
Miscellaneous	3.8

With the accumulation of records of metabolism measurements it has become possible to work out basal values for people of all ages and to establish curves for the general trend of metabolism. General deductions have been charted and norms worked out whereby the factors which affect nutrition are brought under observation and control.

RESPONSIBLE FOR CHILDREN'S TEETH

In response to numerous requests for information pertaining to the establishing of school dental clinics, an article was published in *Public Health Reports* of November 19, under the signature of Taliaferro Clark of the Public Health Service, setting forth in full a practical plan for the organization of protective and remedial dental work. This could be carried out either through centralized clinics or itinerant school clinics. The necessary equipment is itemized and estimates of costs are made. Emphasis is placed upon diet as an important factor in making teeth resistant to decay.

Mouth hygiene is asserted to be a business proposition bringing more than adequate returns for any outlay in a reduction in the percentage of retarded children in assuring better growth and development of the children and by assuring better physical types. With such treatment as makes the retention of diseased teeth safe for the children, or the removal of teeth supposed to be the source of infection which do not respond to routine treatment, we strike at the etiology of many of the more common maladies which lower the vital resistance and affect unfavorably the development of children. Adequate preventive measures demand dental service for children.

FOOD FOR A FAMILY OF FIVE FOR A WEEK—APRIL, 1920

GOOD SERVICE FROM MOTOR CLINICS

THIS traveling clinic on wheels is touring Alameda County, under the direction of the Alameda County Tuberculosis Association, and is said to be the first clinic of this kind in California. The clinic goes mostly into the industrial sections where the population is largely foreign and who are prone to neglect to have themselves and children examined. As a result of these examina-

Underwood & Underwood.

Children are given a health inventory.

tions, children who exhibit traces of tuberculosis are taken out of school and put under favorable management to combat the condition. The clinic carries all necessary apparatus for making laboratory tests. It was bought and equipped at a cost of \$15,000, and was made possible through the sale of Red Cross stamps. The nurses and doctors are supplied by each county visited, and their services are free to the patients.

CANCER DEATHS INCREASE IN MAINE

There were 888 deaths from cancer in Maine last year, which is the largest number of deaths from this one cause to be recorded in a single year since the reporting of vital statistics was inaugurated in this state. Looking backward over the last twenty years, the difference is plainly marked, figures for 1900 giving but 526 deaths from cancer and steadily mounting, with few fluctuations since that time. It was in 1912 that the cancer death rate passed the 800 mark, and in the eight years which have followed has almost reached 900. During this period, 1915 was the low-water mark in cancer mortality, the figure for that year being but 811, but the following year more than offset the slight decrease in reaching 844 deaths, the nearest approach to 1919's record of cancer deaths.

In the period from 1907 to 1911, inclusive, cancer figures held within the 700 limit for yearly deaths, while before that time, back to 1900, the deaths from this cause varied from 526 to 617.

Of the many forms of cancer, cancer of the liver and of the stomach cause the largest number of deaths, undoubtedly because such cancers cannot be reached by the surgeon. Cancer of the female generative organs stands third in the death toll from this disease. While more women than men die of the disease through the peculiar susceptibility of the generative organs to cancer, more cases of cancer of other types are found among men. For example, cancer of the mouth is very prevalent among men, brought on by excessive smoking. Cancer is caused

by chronic irritation of some part of the body, and the clay pipe, which so many men use, is held responsible for many cancers of the lip.

Health workers and physicians throughout the world are concentrating on the cancer problem, and from the aid obtained by vital statistics and from research work some material steps are being taken in handling the disease. Public education of its causes and the need for early treatment is the primary step in the cancer campaign.

ROCKEFELLER BOARD EXTENDS PLAN

The regular cooperative plan of the International Health Board of the Rockefeller Foundation was enlarged during 1919 and has again been extended to carry the war on hookworm disease and yellow fever into many parts of South America and China. The chief features of their 1919 program were demonstrations in malaria control in Arkansas, Mississippi, and nine additional Southern states; systematic efforts to eradicate yellow fever from Guyaquil, Ecuador. Outbreaks of yellow fever infection in Nicaragua, Honduras, and Salvador were suppressed. The campaign against tuberculosis in France was extended and the measures were continued for the control of hookworm in twelve Southern states and in sixteen foreign countries. Operations under a new public health program were begun in Australia.

The report states that:

During 1919 the first steps were taken looking toward a comprehensive study of public health administration. Preliminary studies were made, dealing with the public health work done by the Children's Bureau, by the Bureau of the Census, and by the Bureau of Education of the Federal Government; a general study of public health administration in Massachusetts was undertaken with the assistance of the State Department of Health; a collection was made of the public health bills which have been presented to Congress, and of the reports of committee hearings and legislative debates on these bills; information on the organization of state, county, city and town health administration, and on the relationship between state and local health authorities, was gathered from the laws and regulations of the various states; data on expenditures for public health purposes by states, cities, and counties were brought together; a special report on hospitals and dispensaries was prepared, and published, and a report on infant welfare work in New York City was revised.

CHICAGO POLICLINIC EXPANDS

The Chicago Polyclinic and Hospital is to be expanded into a huge institution where all types of cases will be treated and patients will be asked to pay only what they can afford. It will serve as a community health center where special care will be given to children, and it is planned to make it the greatest obstetrical institution in the world. Industrially injured persons will also receive special attention, and all modern appliances for reconstruction will be available. Training schools for nurses are a part of the scheme. Courses in practical and theoretical nursing will be given, as well as special work in x-ray, anesthesia, and laboratory. The purpose of the directors is to provide a place where all may secure the highest type of medical service, and no one in need is to be turned away for reason of lack of funds.

AMERICAN HEALTH EXHIBIT IN PARIS

The American Society for the Prevention of Tuberculosis, under the direction of the Rockefeller Foundation, maintains an exhibition in Paris as a part of its campaign against the spread of the white plague. The posters are graphically illustrative, the printed descriptions being in French.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

THE PUBLIC HEALTH NURSE AND THE REHABILITATION OF CRIPPLES

THE present widespread interest in the cripple and the activities inaugurated for his betterment should find stimulus and support from public health nurses and all others who have access to the homes where the cripple is to be found. Someone must discover the cripple and influence him to take advantage of the opportunities publicly provided for physical and vocational rehabilitation.

Every study of cripples in a community has shown that they are hard to locate and, when located, are not easily induced to look with favor upon any plan for rehabilitation. The experience of the federal authorities with wounded soldiers is conclusive proof of the truth of that statement. Even though provided by a generous government with hospital facilities for physical restoration and schools for vocational training and at the same time with a generous allowance for living expenses, large numbers of crippled soldiers could not be found, or, when found, could not be induced to take the advantage offered. One agency reported that only 50 per cent of those who were found could be induced to accept the provision for vocational training for a useful pursuit. One man who had lost a leg expressed the desire "to hibernate."

The cripple who has been dependent for any great length of time is likely to have lost all confidence and ambition. He is too willing "to lie down." This attitude must be changed if he is to take the fine advantages now being offered by public and private agencies. The public health nurse stands in a specially privileged position to discover and aid the cripple. As she makes her rounds she can easily learn of those who are handicapped. Perhaps she will find handicapped men, women, or children in the homes which she visits for the care of some sick person. Having learned of the presence of physical handicaps and having established a contact which is friendly and helpful, she can more readily than others influence the cripple to seek rehabilitation. At least she can bring the facts to the attention of other agencies.

To do this work, the public health nurse needs to have three special equipments. She needs to know the psychology of the cripple; she needs to be a student of physical and vocational restoration so as to see the possible application in each case; and she needs to have a knowledge of all of the public and private agencies which are in a position to provide for rehabilitation.

Equipment with the foregoing knowledge will place the public health nurse in a position of practical influence. If thus equipped, she might well become the emissary of the rehabilitation agencies which provide for physical care, therapeutic appliances, vocational, and retraining.

MICHIGAN CONFERENCE ON NURSING

UNDER the guidance of the state department of health there has been held a notable conference of representatives of all branches of nursing activities and the proceedings are published in the February issue of *Public Health*, the official organ of the Michigan State Department of Health.

The conference marks the beginning of the Bureau of Child Hygiene and Public Health Nursing in Michigan. It does more than that, according to Dr. R. M. Olin, state health commissioner. "It marks the beginning of systematized nursing throughout the state. It means the building of county nursing systems in counties which now have no nursing service, the establishment of health centers, permanent baby clinics, short term rural training schools where graduate nurses intending to enter public health work may receive instruction while working in the field, and a score of other enterprises that will help to sell health to the people of the state, prevent sickness, and restrict the spread of disease."

In outlining the need for greater health activity, Dr. Olin pointed out the ravages of the common diseases of childhood and the most common diseases of all people in Michigan, including pneumonia, tuberculosis, smallpox, and venereal diseases. He emphasized strongly the nurses' part in the prevention and eradication of these diseases. In vigorous language he says to the nurse: "Urge vaccination, teach vaccination, and assist in every possible way to avert a general epidemic of smallpox in Michigan," and again, when he said: "No greater public health service can be rendered by the nurses throughout the state than that proposed in helping to control venereal diseases."

NATIONAL FEDERATION OF SETTLEMENTS

The tenth report of the National Federation of Settlements announces the establishment of a national office, an enlarged budget, and increased secretarial service. An urgent need is felt of a regular bulletin and to provide means of communication between members. A statement of housing norms for different types of community indicates itself as a necessary step to secure proper organization of downtown portions of the metropolitan cities.

The results of the Federation's study of the adolescent boy are to be supplemented by a study of needs of little boys and of the expedients found to be most successful in helping them, and it is expected that the results of the technic developed in case work with families above the poverty line, and the organization of leadership of natural groups, will be gathered, digested and made available to all the workers in this field.

INDUSTRIAL NURSES IN METAL MINING COMMUNITIES*

BY GEORGE MARTINSON, SAFETY INSPECTOR, PICKANDS, MATHER & Co., HIBBING, MINN.

MY EXPERIENCE in the metal mining regions is confined to the Lake Superior district, and particularly to the Minnesota ranges. Therefore, this communication deals with this subject as concerning only this district. However, since conditions are similar throughout the metal mining regions of the United States, some points may be discussed which will be of general interest.

Before considering the question of industrial nurses in mining communities, it might be well to describe the conditions under which our employees live. Approximately one-half of them live in what are commonly called "locations." Locations are communities in which practically all of the houses are owned by the company. They are, as a rule, situated in the vicinity of the mines. Many of these homes have water and electric lights and are rented to the employees at a nominal rate, usually one dollar per month, per room; that is, if a family occupies a five room house they pay five dollars per month, in addition to which they pay a very low rate for electricity and water. All of these homes have large lots, usually 70 by 125 feet, affording plenty of sunlight and air. The remainder of our employees live in villages near the mine. These villages are much cleaner, and more attention is paid to sanitary features in them than in the average municipality. Given these excellent conditions, one ordinarily would assume that the field for the services of a nurse would be limited to caring for the sick and to first aid work. We feel, however, that we have found a much larger field for her services.

Essentials of True Life

It has been established beyond any doubt that a contented workman is more efficient than one who is discontented. Inasmuch as the success of an industry depends upon the efficiency of its employees, it becomes wise to consider their happiness and contentment. If it is within the power of an organization to remove any cause of inefficiency and unrest, it should be done. There are numerous causes of unrest and they present as many problems and remedies. Not the least of these problems is that of keeping the family contented. Elbert Hubbard said: "True life lies in laughter, love, and work." The metal mining industry is well able to, and has been, furnishing the latter essential to a true life for some time; but what has been done to further the laughter and love?

The larger proportion of our miners are of foreign birth. They have settled in our communities with their families. Their foreign born wives have come to this country, usually leaving their relatives across the water. They have been brought into our midst and have been left to shift for themselves. Having no warm friends, they have missed the social life to which they were accustomed in the country whence they came. Finding no social life, it seemed to them that an insurmountable barrier prevented the enjoyment of the social diversions they craved. If this condition existed for a considerable period, what would be more natural than to have them become disgusted with America and its industries, which, in their minds, were responsible for their unhappiness? This unhappiness would eventually affect the work of the husband; for, instead of having his helpmate meet

him with a smile, he would be greeted with a tale of dissatisfaction. Such conditions, no matter how good the working conditions, or how large the pay check, will eventually cause the man to leave the community for one in which he thinks his family will be satisfied. They will move and find conditions in their new home about the same. After a few more moves, always looking for that better place but never finding it, the workman becomes dissatisfied, also, and he begins to feel that the industry is responsible for his unhappiness, and when this idea begins to lodge in his mind, he becomes a comparatively easy prey for the sleek-tongued agitator.

Where Rests the Responsibility

It makes no material difference upon whom the responsibility rests. The condition is here. It concerns us as an industry, and we must prevent it. In other words, we must help supply the joy and happiness which will supplant tears with the laughter which is the first requisite of true life. This recalls a few lines by C. E. Bowman:

There is not a place in earth or heaven,
There is not a task to mankind given,
There is not a blessing or a woe,
There is not a whispered yes or no,
There is not a life, or death, or birth,
That has a feather's weight of worth—
Without a woman in it.

The woman in this case I believe to be the industrial nurse.

Assuming that all are agreed that a nurse may prove a profitable investment, and that one or more will be employed, possibly it may be urged that a trained social worker would be more satisfactory. Since the adoption of the Eighteenth Amendment, the liquor question is not acute. There is no great problem of unemployment to deal with, and, as previously stated, with us the housing problem is better taken care of than in most communities. This being true, we can eliminate the idea of a social worker. There is some need, of course, for work of this kind and it is my opinion that we should have a person who will be able to fulfill the duties of a nurse and social worker as well. By virtue of her professional training, the nurse can be of service to the workers at the time when they are in trouble and most responsive to kindness. After having gained their respect and love in this way, she can begin her social duties.

The foreigner, in common with the rest of us, has a certain pride about himself and his home, and the privacy of the home should be respected at all times. It is, therefore, requisite that the nurse have tact in order to get the confidence of the folks with whom she is to deal. Little Joe Krakovich needs a new romper suit, and his mother would love to have him dress like Jim Fisher, who lives next door; but she is unable to cut out the cloth and make it. On a friendly visit the nurse learns of the mother's wish, and assists her. In a few days little Joe is playing with Jim, and looks just as much an American. Are the mother and father pleased? Of course they are. When selecting a nurse for such a community don't forget the qualification that she must be able to do plain sewing. Of course she should be a graduate of some reputable training school and, if possible, one equipped with a good education before going into training should be engaged.

*Read before the Mining Section of the Ninth Annual Safety Congress, Milwaukee, Wis., September 27 to October 1, 1920.

The nurse should be able to take the lead in the little social gatherings which she must promote. But, after all is said, aside from her professional training, tact is really the fundamental requirement.

The Plan Explained

Our nurses are members of the safety department and do their work under the direction of the safety inspector. They are also responsible to the general superintendent or a manager of the group of mines in the district in which they work. Their responsibility to the physician concerns only the cases which he is caring for. That is probably better illustrated in this manner. The physician, who is caring for a family where there is illness, advises the department of the fact. The nurse visits them and tries to make the sufferer more comfortable and cheerful, explaining in detail any instructions which the physician may have given. Her responsibility to that physician ends when his case is disposed of. In this way, it is almost impossible for the physician to make use of her as an office assistant, or to send her out to apply dressings or do other work for which he is being compensated. The nurse, then, being responsible to the company, may feel free to make any suggestions as to the improvements in our medical service, without feeling that she has overstepped the bounds of professional etiquette. Our instructions to our nurses are simply this:

Here is where our people live. Go out and do your best to help them keep their bodies healthy and their minds free from worry. Sympathize with, and help them in their sorrow. Try and leave each home happier because you were there, and, finally, try to inculcate in them the spirit of love, not only within the family, but for their neighbors and for America. Remember, always, that in their eyes YOU are the company.

Social Work Done by Nurse

These instructions to our nurse may not seem explicit, but it is utterly impossible to lay out a specific plan for her to follow. Of course she makes weekly and monthly reports of what she has accomplished, but the written and spoken words cannot begin to do her work justice. The real report can be attained only by going into these communities and noting the changes which have taken place since the advent of the nurse. We find an example in the case of an ordinary family. One of the children is sick. The nurse calls and helps make the little sufferer comfortable. Before leaving, she teaches the mother a few things relating to the care of the child. She calls at this home often during the period of illness, becoming acquainted with the other members of the family and with their immediate neighbors. She learns the birthdays of the children, calls them by their first names, inquires about their school work; in fact, she is interested in every affair of their daily lives. Soon she has established herself in the neighborhood. She remembers the birthdays of the children and comes to them on those days with some little gift. Soon the people begin to look forward with pleasure to her visits.

The mother of this family has not been in good health, and has dreaded to go to the hospital for an examination. Soon, however, the nurse will suggest this and will make an appointment at the hospital, accompanying the mother on her visit. Perhaps a few decayed teeth are the cause of the trouble. She will prevail upon her to have the necessary dental work done. After this work is accomplished, the mother, being again in good health, commences to take a new interest in life. Then comes a desire to improve her home. She will want new curtains and new furniture, and, naturally, the friend of the fam-

ily, the nurse, is called upon to assist in the selection of this material. She will then wish to associate with her neighbors. The first step in this is usually taken during the canning and preserving season. The folks are brought together in a home, where the nurse has arranged for a demonstration by a person skilled in that work. The friendships formed at this little gathering grow, and probably during the winter they begin to meet at little neighborhood parties, again sponsored by the nurse. After she can associate with Americans, and have the family dress like them, the mother learns to laugh and to live. Then, instead of the workman coming home to a harping, nagging wife, he finds that joy has supplanted gloom, and his home is, as it should be, a temple of happiness. In the home where happiness reigns, there you will find love, not only in the family, but also love of America, its institutions, and industries. When this attitude prevails among the workmen, and America's industries recognize the blessed trinity of laughter, love, and work, we will have made a real start toward the solution of one of the great problems confronting us.

MASSACHUSETTS NURSES MEET

The annual meeting of the Massachusetts Association of Directors of Public Health Nursing Organizations held recently in Boston was made the occasion of a conference to map out plans for future work. The address of Miss Mary S. Gardner, superintendent of the Providence, R. I. Visiting Nurse Association, was especially suggestive in discussing the problems of the Central Governing Board and relations with collated activities. New officers of the Association were elected as follows: Miss Gertrude Peabody, president; Mrs. Henry L. Sherman, of Lawrence, vice-president; Mrs. James W. Russell, Jr., of Winchester, secretary and treasurer; executive committee, Mrs. Herman E. Roberts of Braintree and Mrs. Roger Spalding of Duxbury.

BEDSIDE CARE FOR INCURABLES

That provision for the nursing care of chronic and incurable cases should be provided through the extension of the present visiting nursing service, is the opinion of Miss Mary Laird, head of the Rochester, N. Y., Public Health Nursing Association. The majority of these patients themselves would not want to leave their homes, she said, and their number in almost any community is such as to make prohibitive the cost of caring for them in specially provided institutions. Even a small part of the money required for the support of a hospital for incurables, applied to extending the visiting nursing service, would bring far greater benefits to the patients. From every point of view, a home nursing system seems to Miss Laird more desirable.

No estimate has been made of the number of cases of incurable disease in Rochester now being cared for in their homes.

CANADIAN RED CROSS SOCIETY

The Committee on Journals appointed at the recent meeting of the Advisory and Consultative Committee of the Canadian Red Cross Society met recently in Toronto. The Committee decided to utilize the *Public Health Journal* of Canada as a medium through which news and information as to the activities of the various voluntary organizations in Canada may be given more adequate distribution. Scientific articles and news notes from these organizations will begin to appear regularly in the *Public Health Journal* in the near future.

RECREATION AND THE PUBLIC HEALTH NURSE

BY EMELIE M. PERKINS, R.N., ARLINGTON, N. Y.

DOES the responsibility for the recreation of her community lie upon the shoulders of the public health nurse? Her shoulders are broad, but there is a limit to the weight which she can bear. She demonstrated her value as a bedside nurse some time ago; and then she was intrusted with the preventive care of school children; the discovery, care and education of tubercular and venereal disease patients; the education and care of expectant mothers; and the supervision of babies from birth to school age. The routine work of assisting medical inspectors with the examination of school children is followed during the school year by endeavors to have defects remedied, by health talks which may not be cut and dried, but must be alive, that is, carefully planned, and given with real enthusiasm and interest. The health talks and the discovery of existing needs lead to conferences with teachers, members of the school board, mothers, and active members of the community in regard to the installation of hygienic lavatory conditions, the organization of Parent-Teachers' Associations and Mothers' Clubs, the establishment of open-air schools, hot school lunches, ungraded classes, school playgrounds, and clinics of all kinds. An interest is manifested in home nursing, first aid courses, or Little Mothers' Leagues, and the nurse, glad to impart her knowledge of nursing, forms and teaches these classes. The winter comes and families which exist precariously through the summer slip back into destitution. The nurse must know whether the need is real, and often she must collect food or clothes and distribute them. She must know which families are too proud to ask for help. She must know how to advise an harassed housewife; she must be able to clean and scrub in an emergency. She must always have time to talk things over, or to draw out a reticent patient. She must keep records which will show what her work accomplishes, and often she must give her own work that publicity which she feels that it needs.

This Much Is Required

Every township nurse knows all this; it is a matter of experience, and not of theory with her. She wonders how she can possibly put anything more into a day. And yet, every township nurse does mother her community, and it is hard to set a limit when something as necessary as proper recreation must be left outside. Just as a specialized public health nurse,—a tuberculosis or a child welfare nurse,—is constantly seeing the need of generalized nursing service in her community, so the general community nurse sees the close association of health and recreation, and longs for a recreational director. Rural communities are proverbially conservative: they are not yet fully alive to the need for public health nursing service, and only a few of the larger centers have seen the need for a trained recreational director and have provided for that need.

That such a need exists, there can be no doubt. The general trend of enlightened thought and surely the experience of township nurses, shows that. Mr. Lindemann of the Country Life Association, an ardent and convincing apostle of the doctrine of rural recreation, and the Association itself, recognize the need. Colleges which train for community leadership recognize it, and also the general colleges which send out their graduates with a quickened sense of social responsibility and a slight training

in applied sociology. One of the large women's colleges recently engaged a leader in community singing for one week. He demonstrated, not the theory of community singing, but the actual leadership, to a host of enthusiastic young women. The directing of public playgrounds, games, story-telling, are now part of the college curriculum. Under the caption "Buzz and Gossip in Kentucky," the *Survey* publishes an article describing a play institute at Danville. The article notes in closing:

The general verdict, especially among those who had come a long way from remote mountain districts, was that the Play Institute was worth to them a whole week of speeches, and it was decided to repeat it next year in Lexington.

It is easy to prove to ourselves that we must have a recreational director in our county, or better, in our township, but not so easy to procure the necessary salary for the director and the equipment for the recreational work. Often it falls upon the nurse to decide whether she might better devote a part of her time to demonstrating that need, or whether she should devote it all strictly to nursing work. She has spent three years of intensive training in preparing for nursing. Should she undertake something for which she is not trained, and at the expense of nursing work? Of course, it depends on the personality of the nurse. To some it would be impossible to plan and carry out a program of recreation, and for them there is no problem. There is plenty of straight so-called "public health work." But as to the nurse's intensive training, is there not a question? Undoubtedly she has worked hard for three years, and should be admirably fitted for private nursing at the end of her course, but if she becomes a public health nurse, will she not encounter situations just as foreign to her experience as any she finds in recreational work? The scrubbing and "scut work" of her training are really helpful in district work; the technic, and understanding of symptoms and the course of disease, invaluable. But the short course in district nursing which is the best training yet available to many nurses during their hospital years, leaves them lamentably ignorant of the procedure of organizing clinics and classes, of cooperating with friendly social organizations, of helping the mentally defective and those suffering with venereal disease. Planning campfires, canning clubs, cooking, sewing, and dancing classes is no harder than planning clinics; and finding leaders for them is no harder than persuading over-anxious, reluctant parents to let Johnny part with his tonsils. If the public health nurse is fond of children and of a social disposition, as she is very apt to be, this part of the work will probably offer no more difficulty than the direct health work.

The Pros and Cons

The question resolves itself finally into this: Should the public health nurse ever sacrifice a part of her time to the organization of recreational activities? Under certain circumstances, we would all flatly answer "No." If she does not feel a genuine interest in this phase of health work, and a conviction that it is worth while, she should not undertake it. If she is unwilling to work sometimes in the evening, she should not undertake recreational work. If she is not backed by a strong organization, or if she is in a new field, that is, one experimenting for the first time with a public health nurse of its

own, most assuredly she should not consider it. But is it not a proper activity for a nurse in a well established field, backed by good organization, or even by a few thoroughly interested individuals? No township nurse can possibly do all the nursing work in her own township. That is generally recognized, and a nurse is engaged as township nurse, but with emphasis on school nursing, or emphasis on bedside nursing, or emphasis on prenatal and maternity care. If she is school nurse primarily, she does the rest of the work as well as she can, but she does the school work first. She knows her school children well, and she learns to know their needs. It would be a very tired or blasé nurse who would not wish to help organize a playground, after hearing a dialogue to this effect between two young boys,—a conversation that may be heard daily in almost any small town: "Come on, Fred, let's go downtown to the movies." "Aw, what's the use?" "I dunno, but what else is there to do?" "Well, awright—"

Not that there is any harm in the movies, but there is harm in this frame of mind. A punching bag, a basket ball or volley ball outfit, a carpenter's bench, an active Boy Scout organization, are some of the answers. Venereal disease confronts every nurse. It is a difficult thing to discover and treat. Could not prevention be applied in the form of friendly social dances, even if the facilities for dancing were poor, and the quarters small? Camping trips, hikes, games, all outlets for exuberant animal spirits, are preventives. The relationship of the culinary art to health is obvious, and surely a cooking class which has learned how delicious potatoes may be when they are not fried, will be a practical link between the nurse's health talks and the home. The dancing and the sewing classes, the story hours and parties, are not so evidently related to health, but they are related to the normal development of the child.

Small Beginning Possible

The nurse must start the recreational work in a small way. A playground in connection with the school, with volunteer leaders on Saturdays and after school hours, would be as valuable to the school as the soap, paper towels, and paper cups for which many a nurse has worked hard and long. With the proper backing and volunteer help, other things could be slowly evolved from this. But she must have help. If the community is apathetic and leaders absolutely cannot be found, she must not undertake it. She must have some sympathetic organization or group back of her for inspiration and practical help. She must have at least a few dependable volunteer leaders. She must make it clear to the people backing her that she is primarily a nurse, that she is trying to demonstrate the value of recreational facilities to the community, and that, as far as she is concerned, her present endeavor is merely a demonstration. That is, that the work must stand or fall on its own merits after a definite period of time, as one year. Of course, she is taking a chance in thus devoting a part of her time to work which may be given up. But the Red Cross takes the same chance when it places a public health nurse, and says to the community, "We will furnish this nurse for a certain length of time, after which you must keep her yourself if you want her." The Red Cross did pioneer work in opening up fields for public health nurses, and in placing them; the Young Women's Christian Association is making the development of recreational facilities one of the vital parts of its program. Let us hope that these two powerful organizations will stand back of the individual nurses and their communities in their efforts to

introduce organized recreation as well as health work into their communities.

NURSING CONFERENCE IN MICHIGAN

The installation of the seventh bureau of the Michigan Department of Health, a Bureau of Child Hygiene and Public Health Nursing, with Miss Harriet Leck, formerly superintendent at Grace Hospital, Detroit, and superintendent of Visiting Nurses of New Haven, Conn., as its Director, marked the first assembly of public health and visiting nurses ever called in Michigan. More than one hundred nurses from nearly every county in the state were in attendance, meetings being held in the house of representatives of the capitol building.

The formation of the new bureau enables the Department of Health to cover every public health field in Michigan, there being bureaus of sanitary engineering, laboratories, communicable disease, venereal disease, education, embalming, and child hygiene and public health nursing. The new bureau will serve to unify Michigan's child hygiene and public health nursing programs, working as it will in cooperation with the Red Cross and the Anti-Tuberculosis Association. In fact, the conference of nurses was arranged by Dr. R. M. Olin, state health commissioner; Miss Elizabeth Parker, executive secretary of the Michigan Anti-Tuberculosis Association; and Miss I. Malinde Havey, Michigan Red Cross field worker.

Delegates to the convention were instructed in making of public health posters, viewed various demonstrations at the Lansing Health Center, such as the inspection of rural school children, were shown movies relating to public health and visiting nursing problems, and were conducted through the various divisions of the Michigan Department of Health, the heads of the bureaus explaining just what services county nurses could demand from the Department.

Dr. Olin presided at the opening session, telling the nurses of the Department's proposed plan to have a full time, qualified medical officer as health officer in each of the eighty-three counties of the state. Miss Marjorie Delevan, director of the Bureau of Education, spoke on "The Value of Education and Publicity"; Dr. C. C. Young, director of laboratories, told of "The Relation of State Laboratories to Public Health." After each talk there was allotted time for discussion and questions and answers.

During the afternoon of the first day Miss Elizabeth Parker told of the work of the anti-tuberculosis societies in the state and the general program of the Michigan Anti-Tuberculosis Association. Dr. William J. V. Deacon, director of the Bureau of Communicable Disease, spoke on how the nursing profession can cut down the incidence of communicable diseases. Miss Mabel Rogers, state director of Health Crusade, explained how Michigan school children are learning to play the game of correct living; and Dr. E. R. Vander Slice, of the United States Public Health Service, chose as his subject, "Cooperation of the Nurse with the United States Public Health Service." The evening session heard Mrs. Barbara H. Bartlett, director of public health nursing of the University of Michigan, enumerate, in what was considered one of the most inspirational lectures ever given on public health nursing, the qualities of the ideal public health nurse. Mrs. Dora Stockman, head lecturer of the State Grange, spoke on rural health.

Health centers was the topic discussed Thursday morning by Miss Marie Phelan, assistant director of the department of nursing of the Central Division of the Amer-

ican Red Cross. The Red Cross Nutritional Program was explained by Miss Nina Streeter, of the Central Division of the Red Cross, while in the afternoon Miss Harriet Leck made a report on the St. Louis Conference of the American Child Hygiene Association. Miss Mary C. Trafford, Kalamazoo county nurse, talked on county organization; Miss Elma Bergey, Kent county nurse, on dental clinics; and Miss Katherine Johnston, Infant Feeding Clinic of Grand Rapids, on nutritional work with children of pre-school age.

Before adjourning, the delegates unanimously passed the following resolutions:

- Whereas, we, the public health nurses of Michigan, in conference in Lansing, October 20-21, 1920, recognizing that in unity is strength, submit the following resolutions:
1. Resolved, That we offer our services to the United States Public Health Department through the State Director of Child Hygiene and Public Health Nursing, for the purpose of reaching disabled ex-service men and women.
 2. Resolved, That we recommend to the American Legion of the State of Michigan that in order to meet the present emergency in caring for tuberculous ex-service

men and women that immediate efforts be made to increase the already existing sanatoria.

3. Resolved, That we support the State Commissioner of Health in securing a law to establish a full time, qualified medical health officer for each county in Michigan, and be it further resolved that we support and cooperate with the present plans of the Bureau of Child Hygiene and Public Health Nursing of the State Department of Health.
4. Resolved, That this conference has been of great value to the public health nurses of Michigan, and we would therefore respectfully request that the State Department of Health arrange for frequent state and district meetings and we would suggest that the districts of the State Nurses' Association be used as the unit whenever possible.
5. Resolved, That while continuing to support and cooperate with the Public Health Section of the Michigan State Nurses' Association but, whereas, the public health nurses of the state realize the benefits to be derived from contact with those of the medical profession who are interested in public health and members of the Michigan State Public Health Association, we respectfully request that a Section on Public Health Nursing be created in the Michigan State Public Health Association.

THE VISITING NURSE ASSOCIATION OF CHICAGO— ANNUAL REPORT

By EDNA L. FOLEY, R.N., SUPERINTENDENT, CHICAGO, ILL.

LAST week I asked a friend who knows nothing about visiting nursing what she would be most interested in hearing discussed in an annual report. She said, briefly, "results"; therefore, thinking that all may be of the same mind, our annual report is going to tell something about the results of hundreds of thousands of visits paid to our more than thirty thousand patients during the past year.

Messengers of Hope

This large number represents more than twenty thousand individual homes. To six thousand, or not quite 20 per cent, of our new patients, we went as old friends, for sometimes our records show that we had been in those homes before, or more often than not some member of the family supplied the missing information. After a rather bad struggle a visiting nurse was successful in helping a young girl back from a very serious attack of pneumonia. The father, a man over thirty, had not seemed unduly alarmed even when the condition of his young daughter was at the worst, because, as he afterwards explained: "I knew you could do it; from the first minute I laid eyes on you coming in that door, I knew it was all right with Mary. You see, more than twenty years ago, when I was only a kid and my mother was dying with the same thing, a girl like you, with a blue coat came in. Ma had no chance, they said, but if you want to hear her tell about it, she is only two blocks away down the street. I have never seen the blue coat from that day to this, but as soon as I saw it, I knew that Mary was safe."

Mary is lost now among the 18,956 patients dismissed "recovered," one of the "results" with which we are modestly content. An aggregate of 5,052 patients dismissed "improved" is not a bad showing. One of them, the young mother of three small children, limped gaily into our Christmas party as if she had never had a care in the world. Just four years ago this month we were asking you to give her a rocking chair, as the 1916 epidemic of

poliomyelitis had left her apparently hopelessly crippled. Home visits, consultations and orthopedic surgeons, treatments, braces, crutches, three years of hard work, and then, presto, she is dismissed "improved," not needing braces, discarding crutches, her four room flat a marvel of tidiness, and herself able to get downtown to do a little shopping off and on. Can one ask more of so simple a word as "improved"?

Our next classification of dismissed patients, "unimproved," is not so pleasing. In this discard, 4,262 are totaled, the saddest being the young mothers and their tiny babies whom we must discharge "unimproved to midwives," for we do not give care to any patients who do not employ physicians. Occasionally this rule seems a very hard one. There is an old man on the West Side who stubbornly refuses to call a doctor for his injured leg because "the nurse dressed it once and done it right smart and he won't stand for the foolishness of calling a doctor." Unfortunately for his peace of mind, the commonwealth has never given us the right to practise medicine; consequently, the home-made attentions that his poor leg is receiving are rapidly making a bad matter worse.

Of our patients, 862 have died in their homes. One poor soul's release came last Easter after months of dreadful suffering. A furious blizzard ushered in that day. Easter Monday the lonely husband said brokenly to the visiting nurse who went as usual to do the daily dressing: "Nobody else came. Her mother was snow-bound on the North Side and couldn't get here, and my sister was tied up in Indiana and she couldn't come. I telephoned other friends, but they couldn't come, either; they said there was nothing that they could do. Once I thought that the wind had blown in the door, it blew so hard, but I looked up and saw that it was the visiting nurse. There wasn't much she could do, either; there wasn't much anybody could do, but it was heavenly brave of her to come and it sort of eased the end a little."

In all, more than 30,000 patients were dismissed from our books, and of these less than 900 were not traced because of wrong addresses. An incorrect address is the bane of a visiting nurse, for it doesn't help her at all to travel to 6400 South when a little forethought on the part of the person sending in the call would have guided us to 6400 North.

Where Patients Come From

People frequently ask how we find our patients. We don't find very many of them, they come themselves. About one-third are referred to us by employers and the Metropolitan Life Insurance Company, whose industrial policyholders, when ill, are given care by our service. About one-fourth are referred by physicians; families themselves telephoned in more than four thousand; hospitals, dispensaries, and other agencies sent the remainder.

Visiting nursing is difficult work. One seldom knows when going to a new call whether the patient will present a medical, social, or economic problem. Sometimes all three confront a nurse, and consequently all three kinds

MISS EDNA L. FOLEY, CHICAGO.

of training really are needed to fit her for the decisions and work that await her in many homes. Conditions rarely seen in general hospitals are of frequent occurrence in district homes, and the nurse must have nimble wits and a good hospital experience if she is going to be able to handle six or eight different types of cases in one day, to say nothing of six or eight different types of families.

This is one reason why the work in the districts is carefully watched by a staff of supervisors whose number we should like to see increased. Last winter a supervisor paid an emergency visit in the house of a choirboy who was very ill with pneumonia. She had only to take his pulse to discover a very unusual symptom, a faint but slow pulse, not the usual rapid one that accompanies this high-fevered, hard-breathing condition. On questioning the mother she ascertained that medicine, ordered every two hours, was being given hourly as the boy grew worse; for the mother, although in many respects a most intelligent woman, had reasoned that if a little helped, a lot might do better. The medicine was stopped, the doctor summoned, a special nurse put in the home for forty-eight hours, as much to give the over-wrought mother a rest as to care for the boy, and the patient made an uneventful recovery. A nurse who could shake down a thermometer but had never been taught the significance of pulse rate and quality would have been of no special assistance in this particular home.

Nursing is variously defined by its friends and adversaries. Some people would have you think that any creature in petticoats can be a nurse; others that all nurses are angels of light and messengers of glad tidings. There is a devoted daughter on the South Side who knows that an untrained person can't develop into a full fledged nurse after a few lessons, for an over-zealous visiting nurse tried to assure her that any intelligent woman could give her old mother, lying in the semi-conscious condition that so often follows a stroke of apoplexy, the simple nursing care that the patient required. The care was only bathing and feeding, and one or two other simple treatments. Many mothers understand them and can give them quite well; but the nurse had failed to take into consideration the fact that the patient was very heavy, that the weather was very warm and that the bathing, sponging, and rubbing in addition to the other treatments required a skill born of long practice. As the daughter said afterwards, "She was a very good nurse except that she did not speak the truth. She said that I could give mother just as good care as she gave, and I couldn't; for I tried it and we were both miserable until the nurse came back the next day. Now everything is all right again." To some people a patient in that condition is just an uninteresting old woman, but to devoted children such patients are mothers and fathers, and the best nursing procurable is not too good for them, whether or not the patient is able to appreciate it.

Carried into New Year

We entered the new year with more than two thousand patients forwarded on our books, many of these being acute cases whom we trust will convalesce rapidly and be dismissed into our "discharged, recovered" class. There is one man in the group to whom the nurses have been going very faithfully—in fact, last week a visiting nurse was approached by a little old woman while she was waiting for a street car out on the edge of one of Chicago's big prairie districts, and, without any other preliminaries, the little lady said, "I don't know your name but I must speak to you. I always have to speak to girls in your uniform, for one of you has been coming to my house every day for the last three years and she makes it possible for us to keep our home together. Never, so long as I live, shall I forget what she has meant to us." An extensive, painful, and, to many, repulsive dressing done daily, although the patient be a long suffering little man, might not seem to some people constructive work; but when you consider that faithful service in this one home alone has enabled an elderly couple to keep their home together without further outside assistance, we believe that visiting nursing not only requires the highest type of skill but the warmest kind of a heart.

Our staff has grown very large and we are doing all sorts of work, but from the earliest years of its history the Chicago Association has been more or less famous for the nurses that have gone out from it to all parts of the earth. During the past year we have heard from our former visiting nurses in China, the Philippines, Serbia, Poland, and France; and there is hardly a state in the Union in which some one of us has not worked. Only recently we have heard from nurses in Texas, Kansas, Ohio, and Colorado. Just last week we got the following letter from a nurse who left us more than two years ago:

School work has kept me very busy this past month, as we have had a smallpox epidemic. During the height of the epidemic more than sixty families had it. In one family the father and six children were ill and, to make matters worse, the mother gave birth to a baby boy. I

urged vaccination last fall, but it took a little time before the school board passed on it. We kept the schools open; in fact, in a small town, where people think less of having smallpox than of being vaccinated, it was really the safest thing, but it was work to discover all of the cases. During the height of the epidemic the city council wanted me to investigate all suspected cases in the homes, and a machine was placed at my disposal. The mornings were spent in the schools and in the afternoons visits were made all over town and sometimes four miles out in the country. In one place, three miles out, a school child had every evidence of smallpox, but the mother had thought nothing about it and had called no physician. She told me she was going to town that afternoon to visit her sister, just operated upon at one of the hospitals. Needless to say, she did not go. Rich and poor were affected alike, and quarantine signs were seen all over town. There are many problems to meet, even in a small community, and to have no one to turn to for advice makes it difficult at times.

It is just such nurses as this, who are brave enough to do their duty in spite of its difficulties, that the National Organization for Public Health Nursing is trying to help by serving as a national information bureau, a library center, and clearing house.

Factors in Family Comfort

We have found our people far more comfortable during the past year than ever before. Even in this period of depression, a surprising number are living on savings or on neighborhood credit and, although many men are out of work, they are asking jobs, not relief. Of course, higher wages and lessened immigration have much to do with this state of affairs, but we believe that prohibition has been no small factor. Not all of our homes are so comfortably fixed. In one the visiting nurse found no evidences of any comfort except a Victrola. Broken chairs, poor beds, and a lean cupboard were perfectly visible; but on the center table, proudly put forth in sight of everyone, was this wonderful Victrola on which, as she learned, the family was paying fifty cents in alternate weeks, though they were still paying two dollars a month on a Liberty Bond. As Liberty Bonds and Victrolas are seeming luxuries on an eighteen dollar a week wage, it is not surprising that the Victrola possessed only one record, but before the patient could be introduced and given care, the nurse had to sit on a rickety chair in a cold room while the family solemnly played that one record through for her. It is difficult for people who have many pleasures in their lives to realize how much the poor will frequently sacrifice for the sake of beauty that we accept unconsciously or as our right.

A year ago I was in Italy working with some Italian nurses, and I asked one of them, whose English was far better than my Italian, what she considered the most outstanding difference between Italian and American nurses and, to my amazement, she said very seriously, "You never give up, you hold on. If Gabriel himself came for the patient, you would shut the door and keep on working." And then she went on to tell me that she had been in the American Hospital in Rome where an American soldier boy was dying of typhoid fever. The physician and the priest had left, saying that they could do no more, and she had just settled herself comfortably in a chair by the bedside to await the end, when an American nurse came in, scolded her because the ice cap was not properly filled and applied, adjusted the curtain to keep the sunlight from the bed, fixed the pillow so that the position of the boy's shoulders was changed ever so little. Every few minutes that nurse came in and did something, and finally the bewildered and indignant little Italian, in no uncertain tones, reminded her that the boy was dying and should be allowed to die in peace. To her amazement,

the nurse replied, "You don't know whether he is dying or not; unless you work over him you may help to kill him. In America a nurse never gives up."

Somewhere in Rome today a young Italian nurse is doing her best to save the lives of little babies in miserably poor homes—homes so much poorer than anything we have in Chicago that Chicagoans would hardly believe if one were described here—and all because an Italian nurse has just as much pride in her work as any American nurse, and if her sister overseas can never give a patient up, she can't, either.

In spite of its difficulties, the visiting nurses like their work, and their motto, too, is the motto of the American nurse in Rome; for so long as the family and the patient allow us to fight, we, too, never give up.

PUBLIC HEALTH NURSE

The *Public Health Nurse* for February, 1921, contains a discussion by Lee K. Frankel on the decreasing mortality rate as resulting from the extension of nursing service to industrial policy holders. For an expenditure of a million and a half dollars for preventive work among industrial policy holders in the year 1919, he says, the Metropolitan Life Insurance Company effected a reduction of three and a half million dollars in claims and a saving of 18,000 lives that can be accounted for only by the health work done by the company. In more detail, the percentages of mortality reduction for certain diseases in the industrial class from 1911 to 1919 have been as follows: typhoid fever, 68; acute infectious diseases of childhood, 46.5; tuberculosis of the lungs, 30.2; organic diseases of the heart, 19.7; Bright's disease, including nephritis, 25; and puerperal septicemia, 23.9. In every case the company's reduction has been greater than the corresponding decrease in the entire registration area; and, especially since this reduction is most marked in those diseases which, like typhoid fever, diseases of childhood, tuberculosis of the lungs, and diseases of maternity, have been most subject to the company's nursing service, it is fair to say that the nursing service has been in a large measure responsible for the relatively greater saving of lives among policy holders than in the general population. The same issue contains articles of interest by Lois Stevens on "Mothers of Our Race," and on "A Definition of Nursing," by Miss Edna L. Foley.

THE PREVENTION OF HEART DISEASE

The Association for the Prevention and Relief of Heart Disease held its third annual meeting at the New York Academy of Medicine, February 7, 1920. The activities and plans of the Association were discussed by Dr. Haven Emerson. The plans for the ensuing year, including the further development and application of measures which will prevent heart disease, will seek to provide occupations suitable for cardiac patients, and will promote the establishment of special dispensary classes for patients with heart disease. Significant figures were presented on the incidence of heart handicaps. Not less than 20,000 children in the public schools of New York City come under this category. At Bellevue Hospital alone last year there were treated 781 patients suffering from advanced stages of heart disease and 10,421 deaths were caused by organic heart conditions, in comparison with deaths from tuberculosis, which numbered 7,396, and from cancer, which numbered 5,141. The following members of the Board of Governors were elected: Dr. F. Stuart Hart, Dr. John W. Brauman, Dr. Robert D. Halsey, Dr. Charles Hendre Smith, and Dr. E. G. Stillman.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

HEALTH OF THE SCHOOL CHILD

THE responsibility of the school for the health of its pupils is being realized more fully than ever before, and is one of the favorable indications for a marked advancement in the physical status of our people. It is believed and expected that many of the ailments of later life, including the so-called degenerative diseases, will be materially reduced on account of the improved physical condition and better personal hygiene in youth. Society's supervision over the health of the child during the period it has set aside for the development of his intellect is due to the recognition of the close relation between the physical and mental condition of the child, also to a growing feeling that the child's health is just as much a social responsibility as his education.

The extended employment of medical inspectors, school nurses, and physical training teachers, and instruction of both the teacher and child in the fundamentals of healthy living, have been productive of markedly beneficial results. Reduction in the absenteeism from school, lowering of morbidity from communicable diseases, and improvement in the child hygiene are some of the definite advantages ascribed to the school health campaign. With the further development of these activities, careful studies relating to physical defects or particular phases of the school health problem have been carried on and have contributed materially toward increasing the efficiency of this movement.

A recent report of the United States Bureau of Education based on the result of examination of eyesight of school children in all parts of the country can well be considered an urgent plea for immediate attention to the problem of conservation of child vision. Approximately 20 per cent of all school children are in need of eye-corrective treatment, but the solution of the problem rests not only with the detection and correction of these defects, but more especially with the removal of the causative factors responsible for these conditions.

The report includes a careful study of the environmental conditions unfavorable to eyesight, including classroom lighting—natural and artificial—color of walls, location of windows, position and condition of blackboards, size and comfort of desks and seats, size of type in printed books, and effect of moving pictures. The educator's view of the problem is expressed by Dr. Claxton,

who states that¹ "the fact has been demonstrated that there is a progressive increase of eye defects with grade progress in the schools. It is clear, therefore, that the care and protection of the eyesight of school children is a school duty and a school problem. It is incumbent upon the schools not only to discover defects and disabilities that impede growth and interfere with school progress, but also to make the conditions of school life and school practice such as will conserve and promote the physical and mental fitness of the children."

Investigations by the United States Public Health Service and others testify to the wide prevalence of dental defects among school children, frequently more extensive than all other defects combined. Of twenty-five hundred rural school children examined, 49.3 per cent had two or more decayed teeth, the highest percentage being found among eight year old boys and seven year old girls.

Dental defects may seriously injure the growth and development of the body and lower the child's resistance to communicable disease. In a plan for organizing protective and remedial measures for conserving the teeth of children, Clark and Butler² of the United States Public Health Service recommend the establishment of dental clinics, centralized and itinerant, for preventive and corrective dental work, and also education of the teacher, child and parents in the fundamentals of mouth hygiene. These measures are being carried out with effective results in many parts of the country. JULES SCHEVITZ.

INCOME FACTS IN STUDYING DISEASE

The occurrence of most diseases is more or less dependent upon certain sets of conditions that are governed by the family income, says Edgar Sydenstricker in a recent issue of the *Public Health Reports*. The partnership of poverty and ill health has become proverbial.

The various methods of classifying families according to income are discussed and the derivation of the "Fam-main" scale explained. Other scales were developed to take into account differences in size of groups and sex and age composition, in the effort to bring the varying groups into comparable classification. The scales, as worked out in this valuable paper, seem to be applicable to all wage earning groups and the use of these scales would be decidedly preferable to former methods of classifying families on the basis of net income for the family as a whole. The usual methods of classifying families by income groups, by per capita income, or by families of similar size have a much more limited application.

OBSERVATIONS ON THE INFANT MORTALITY RATE AS AN INDEX

BY DWIGHT M. LEWIS, M.D., DIRECTOR, RURAL SANITATION, WEST VIRGINIA STATE DEPARTMENT OF HEALTH,
CHARLESTON, W. VA.

SUBMITTING that the infant mortality rate is the most delicate sanitary index of a community, I am prepared to show that it is an index of the amount of preventable communicable diseases, both filth borne and respiratory in origin; it is an index of the amount of preventable defects of pre-school and school age; its delicacy may be resolved into one of localization of preventable diseases and such defects as constitute factors for the further spread of such preventable diseases. In reverse, the absence of such defects or the absence of the preventable diseases determines a possible absence of infant mortality both in urban and rural communities.

Sanitarians of today, like those of the past, agree that infant diarrhea is a factor in the reduction of infant mortality. The sanitarians of today know this from the application of the prevention of infection. Whether it is in terms of pasteurized milk, as advocated by New York City, or in terms of prevention of flies and fingers carrying infection from the diapers of those ill with diarrhea, as in Richmond, Va., or in terms of clean milk, as advocated and practiced by us in New Haven, Conn. (and, it should be remembered, the latter included measures against tuberculosis), all three such practices had the definite basis of "application" of scientific methods against the spread of disease. The reasoning of the sanitarians of the past was that agreement of "logic."

As Relates to Respiratory Diseases

Absence of further commensurate reduction of infant mortality may be shown today to be definitely proportionate to the absence of continued reduction of the incidence of, and the mortality from, the respiratory diseases. That such absence of reduction lies exactly in "logical" reasoning rather than in the application of scientific observations has been shown by the author¹⁻² during five years of municipal field experience in the control of the communicable diseases. The study of vital statistics of all respiratory infections not only in terms of reported cases and deaths but of investigation of unreported cases as well, together with consideration of the errors of diagnosis, gave two very definite conclusions: (1) That there could be shown a hitherto unknown interrelation and interdigitation of the various respiratory diseases; (2) that in no less certain terms than that of diarrheal diseases, respiratory diseases are a factor in infant mortality. The application of field observations in respiratory diseases to the reduction of the infant mortality rate gave definite results as compared to the previous years in our city where no such measures were taken. Comparisons made with both such time periods of the vital statistics of neighboring cities were confirmatory. The cities compared had similar birth rates and similar constituent foreign born populations.

At that time consideration was given to the possibility that congenital debility and malformations were susceptible of analysis from the standpoint of communicable respiratory diseases. Later I showed by a graph of the

vital statistics of the weekly mortality figures as published by New York City for a period of two years, agreement in the curve rates for infant diarrhea, respiratory communicable diseases and that for congenital debility and malformation.³ In no less certain terms than this graph do we again have such confirmation at the present date. The weekly *Bulletin* of New York City shows a low record for 1919 of infant mortality. For 1920 the rate was higher and the one concurrent rise in any other group of diseases that was proportionate, and of the same time period, was the increased mortality from measles under ages 5 and 1. At and following this time period there was also an increase in mortality from congenital debility and malformation. There was, then, evidence that the residuum of congenital debility and malformation is during those periods of least infant diarrhea and communicable respiratory disease: that engrafted on that residuum may be found proportionate waves with increased both types of disease: that such maximum waves of congenital debility and malformations are during epidemic periods of both types of disease—infant diarrhea and communicable respiratory disease.

If now we read into the present day pre- and post-natal care, not the logic of personal habits and hygiene, but the applied science of prevention of communicable respiratory disease as well as that of infant diarrhea, what further facts or observations are on record for confirmation.

Brend,⁴ from the study of the voluminous statistics of all England, concludes that the ruralization of all individuals is the solution of reduction of infant mortality beyond that gained by the control of infant diarrhea. This author places himself on record that the present day method of combat by the detailed pre- and post-natal care has been of very little avail, as evidenced by the record of the city of Bradford, where all such measures had been in effect since 1910. He states that the measures that will benefit all children and all classes are those which reduce mortality in the first year of life. The conclusion of ruralization is reached by "logic," in the same terms of unpolluted atmosphere as is needed for the young plant life. In accord with the author named, our published results of the reduction of infant mortality are pre-eminently the measures for the reduction of mortality benefiting all children and all classes.

We can now place on record our observations from the experience of one year's intensive work in rural county health work, which work confirms our municipal experience. Like the latter, our rural work has been the personal field experience based on house to house survey work in terms of all communicable disease and deaths, of births, and deaths under age 1, and of the examination of school and pre-school age children for the major defects. In a recently published article⁵ I gave the observations based on a first survey of a rural county, predominantly agricultural in population, covering a three months period. The results as found and published were

1. Lewis, D. M.: Prevention in Public Health, Bost. M. and S. J., April 15, 1918.

2. Lewis, D. M.: Infant Mortality: Theory and Results, Bost. M. and S. J., October 17, 1918.

3. Lewis, D. M.: Reduction of Infant Mortality, MODERN MEDICINE, March, 1920.

4. Brend: Health and the State, Constable & Co., London, 1917.

as follows: The sum of all the agricultural areas had for the year 1919 a birth rate of 24 per 1,000 population and an infant mortality rate of 19. The sum of the industrial areas has for the same year a birth rate of 32 and an infant mortality rate of 80. One agricultural district had had an absence of infant mortality for each and every year of the five year period that the survey covered. Yet in the district mentioned the births showed an average yearly rate of 12 for the five year period. Offered in contrast was the highest rate of one industrial district with an infant mortality rate of 400. The relation of the mortality rate from communicable respiratory diseases and the infant mortality rate was shown in a published table. It was as follows:

TABLE I.—COUNTY SURVEY (Corrected).

District	W1	B1	M	B2	W2
Population	533	669	1114	1205	1664
Mortality rate respiratory diseases	0.0	8.96	2.8	14.9	4.2
Infant Mortality rate	0.0	68.00	17.0	82.0	50.0

There was further given a table showing how low was the communicable respiratory incidence and deaths from each and all the usual diseases during the five year period.

Brend¹ reasons with a qualification that measles and whooping cough should show as great an incidence in rural life as in urban. His reasoning is that where there is a school house, there those diseases are spread. His qualification is that we do not know the actual number of cases of the diseases mentioned in rural districts. From this standpoint as well as from the notably low incidence of communicable respiratory diseases that obtained in the county surveyed, a study was made of the incidence of measles in the rural areas. In that rural district mentioned as having had no infant mortality for the five year period, 66 per cent of the 263 children examined never had the disease; further, 51 per cent of the children who had escaped the measles were over ten years of age. In another remote area, equally lacking in railroad facilities and even road facilities save in summer, 71 per cent had never had the disease and 72 per cent of such children were over age ten. Further, the "flu" of 1918, 1919, and the February wave of 1920 had been a stranger to the two areas mentioned. Inasmuch as Brend shows that the death rates from measles and whooping cough are much higher in industrial areas than in rural areas, other observations that we have made are of importance in their bearing on the subject. A study of measles and pneumonia in army cantonments gave the same evidence that I had found in municipal life. In an article published in this journal² the death rate from measles is shown to be dependent on the concurring frequency of broncho-pneumonia. The simultaneous rise and their proportionate rates, predominantly in rural camps or camps made up of rural drafts, was evident on the huge scale of thousands of young adults. Our municipal experience was in terms of children with a lesser content of rurals. There is now corroboration from our rural experience. An excellent illustration of the relationship of measles and broncho-pneumonia was related in the recently published article mentioned.³ We can bring further evidence to bear from our results of the examination of children. Our urban results in the reduction of the sum of respiratory as well as of specific respiratory diseases, predominantly diphtheria and streptococcal infections, were due to the finding of and control of the car-

riers of respiratory germ diseases, predominantly diphtheria bacilli and streptococci, and, to a lesser extent, pneumococci and the meningococci. As contrasted with a 2 per cent content of diphtheria carriers among children in a population of 165,000, following a frequency of respiratory diseases and an unusual frequency of reported and found cases of diphtheria,⁴ we found no diphtheria carriers in the similar period of winter in 1920, during and subsequent to the "flu" wave in the examination of 1,763 rural children. There were found, as has been published,⁵ three respiratory carriers; one was apparently pneumococcal and the other two were streptococcal.

Problem One of Disease Carriers

There may, then, be in rural areas a low incidence of communicable respiratory diseases and there may be found a low carriage incidence of humans of the specific disease, as well as of that disease which is the chief factor in complicating the primary disease. Parallel to such low incidence of communicable respiratory disease and its continuance as low, is the continued low or absence of infant mortality. Is there not, then, evidence that we may with both "logic" and with "applied science" better express the atmospheric pollution of Brend as the demonstrated atmospheric pollution of respiratory communicable diseases? Such scientific application holds in the absence of such human carriage in rurals as holds in the rise and fall of the diseases in cities. How such carriers are made and continued was shown in an article dealing with municipal health work.⁶

In further corroboration of the intimate relation of communicable respiratory diseases and infant mortality, we now present the evidence from a second county survey among a predominantly industrial population, rural in

TABLE II.—INCIDENCE OF DISEASE. THE FIRST FIGURE IN DOUBLE COLUMNS INDICATES THE NUMBER OF CASES. THE SECOND GIVES THE NUMBER OF DEATHS. TOTAL BIRTHS AND TOTAL DEATHS ARE SHOWN IN LAST DOUBLE COLUMN.

District	Population	Year	Diphtheria	Infant diarrhea	tuberculosis	Amtharia	Leasae	Scarlet fever	scapitis (epidemic)	Follongitis	whooping cough	Total Pneumonia	Births

the sense of population only. Due to a content of 13 per cent foreign born population and upwards of the same percentage of negroes, and the fact of continual shifting of parts of the population, the statistics from this county have a content of venereal disease which should be considered if absolute relations in terms of our discussion are sought. As our article is in terms of a predominant problem, the facts are mentioned only for the sake of interpretation of minor lack of agreement of statistics. Table II gives the incidence of and the deaths from the respiratory and filth borne diseases for the last two years of the five year period taken together with the births and deaths under age one for the various communities surveyed.

Examination of Table III shows the contrasting mortality rates for respiratory communicable disease and infant mortality rates for the various communities obtained from Table II. It is to be noted that in 70 per cent of the communities or areas that there is a comparison of rates, more or less proportionate, though generally less proportionate than in Table I. Exact proportions may not be expected, for the reasons given as well as from the fact that the birth rate of the surveyed communities or areas was 48 for each of the two years as compared to the industrial areas of the other county of 32 or that of the agricultural areas of 24.

Tables II and III, like Table I, show that even in industrial districts congenital disability and malformation as a factor in infant mortality may be a negligible one in the face of a predominant factor definitely infectious, and in parallel with the incidence of, and the mortality from communicable respiratory diseases. Based on death certificates of cities and the country, we are told that 40 per cent of deaths under age one are from congenital debility and malformations. Brend's statistics of total mortality for all ages per 1,000 children born are enlightening. Brend's rural south areas have a rate of 65.53 per 1,000 born, as contrasted with the industrial north of 129.77 per 1,000 born. Inasmuch as the north areas mentioned are those characterized by "smoke hanging over, cutting off 20 per cent of sunshine and 40 per cent of the total light," and atmospheric pollution is thereby reasoned, the analysis of the total rates given is of value. There is a 438 per cent excess of total respiratory and diarrheal diseases and a 37 per cent excess for prematurity and congenital debility and malformations of the north areas over the south. In a former article mentioned we gave the total mortality of all ages per 1,000 born in the agricultural areas as 66 and the industrial areas as 112. We also analyzed the deaths from the 61 per cent of obtainable causation of death in the industrial areas. The figures were 72 per cent from infectious diseases, 14 per cent from accidents, 10 per cent from prematurity, and 4 per cent from constitutional diseases. Table III shows that the excesses of infant mortality are localized in the same industrial area and that they are mainly those of communicable respiratory disease. An analysis of Brend's industrial area does not bear out Brend's logic. It does bear out the concurrence of his results in terms of communicable respiratory disease. There is further accord with Brend's statement that "the chances of survival differ but little at birth in town or country, but the noxious influences of the former soon come into play, making themselves felt as the first year of life progresses, to yet greater extent in the second and third year, when the urban excess approaches 100 per cent, and thereafter gradually declines."

We have, then, very definite evidence that congenital debility and malformations has been and is the waste

basket for missed and uninvestigated endemic communicable diseases, predominantly respiratory.

School and Pre-School Age Defects

Only on completion of the statistics of the survey of the second county were we impressed with the possible relation existing between these two fundamentals of health work. Table III shows the very definite relation between the infant mortality of communities on the one hand and the percentage of nose and throat defects of the children of that community on the other hand.

TABLE III.- PROPORTIONATE RELATIONS OF THE DEATH RATES FROM COMMUNICABLE DISEASES AND THE INFANT MORTALITY RATE.

Community	Infant Mortality Rate for year					School age defects		Mortality rate 1918: communicable diseases	same 1919	total school children examined	total pre-school
	1915	1916	1917	1918	1919	School	Pre-school				
E-W	66	155	55	50	59	40	39	4.1	5.8	287	440

H	74	60	42	67	0	40	36	5.9	2.9	108	116
C	125	100	154	166	59	46	44	20.2	11.6	33	54
T-F	100	175	118	136	120	31	51	9.9	3.9	48	101
Mo	0	71	0	77	0	31	47	9.4	6.3	55	55
G	0	91	267	0	158	32	50	0.0	0.0	28	66
S	0	77	0	154	46	38	58	5.7	0.0	34	64
B	0	83	111	154	0	33	33	9.3	0.0	43	49
M1	154	267	200	95	67	50	41	16.3	3.2	50	61
	0	47	143	45	0	37	44	2.3	4.6	63	86

The existence of any constant between the infant mortality rate and the percentage of nose and throat defects should not be expected of the table, as the examination of the children was upwards of one-half year following the record of infant mortality. This alone explains the discrepancy in the figures of community T. F., where the recorded defects were subacute ones subsequent to and consequent on a frequency of septic sore throat that had been prevailing for some three months. Of interest is community R. F. B., which was an exception to the agreement of yearly infant mortality and respiratory mortality rates. The defect percentage in this community shows agreement with the yearly infant mortality rate, and from the morbidity of communicable diseases in Table II shows that the mortality rate may not be the true rate, by reason of errors of diagnosis. Inability to reach but upwards of one-half of the children in community S. is a reasonable accounting for the community being an exception to agreement of the infant mortality rate and defects percentage.

Preventable Diseases and Defects

Summary of the intensive work on the three fundamentals of communicable diseases, infant mortality, and defects of children in industrial communities as shown in Table III is a rather clear cut picture that needs little comment. Our present day knowledge is that defects of the naso-pharynx are an index of resistance to communicable respiratory diseases. Should we further read into the table the known fact that our communicable respiratory disease carriers are those with naso-pharyngeal defects, and by field demonstration add such work for successful combat of the respiratory diseases, the interdigitation of infant mortality, communicable diseases respiratory in origin, and the naso-pharyngeal defects of human beings becomes rationalized through this ability to localize areas for resultful work and the measures that may gain the results.

Not only in rural areas where communicable diseases have been low in incidence, or even absent, but in industrial areas as well, under similar conditions, we can show parallel absence of infant mortality. The importance of this is great, inasmuch as it is exactly in such districts that "logic" reasons educational work as the greatest need in welfare work for the purpose of reducing infant mortality. Only after analysis, then, of the existing conditions of the industrial district may there be the intensive, resultful, continued increase of "community health." The failure of continued decreased infant mortality is rather exactly in terms of Brend's statement regarding the city of Bradford and applicable in many cities. Localization of absence of infant mortality may be shown in communities where no public health work has been done; what has been done, or better, what has happened, is the parallel of such absence of infant mortality and the absence of mortality from the communicable filth borne

and respiratory diseases together with that of the low content of defects of nose-throat in children of school and pre-school age.

In sum, infant mortality rates may be used as an index to check up and be checked up by the other fundamental units of health work. By vital statistics, by morbidity of communicable diseases, and by examination of the naso-pharyngeal defects of children, we may analyze the delicacy of the response in the infant mortality rate. If into the present day teachings of the physiology and pathology of the habits of life we translate these facts of the medical and surgical physiology and pathology of the naso-pharynxes of humans with respiratory disease and with defects, there will result better directed and more fruitful efforts toward the prevention of disease. We can through such work show the why, when and where of the delicacy of the most sanitary index of a community,—the infant mortality rate.

EXAMINATION OF FOOD HANDLERS FROM STAND-POINT OF TUBERCULOSIS*

BY M. J. FINE, M.D., DIRECTOR, TUBERCULOSIS BUREAU, NEWARK DEPARTMENT OF HEALTH, NEWARK, N. J.

OCCUPATIONAL disease and hygiene have long been recognized as an essential health problem. In the food handlers, not only the personal factor of the employee, but also the contamination of articles of diet, and the spreading of communicable diseases must be considered. Compulsory physical examination of all individuals in contact with food prepared for or sold to the public has been instituted in many cities with startling and beneficial results.

Profit by Prevention

The efforts and expenditures in instituting such a system are vastly repaid by the results obtained. The city profits by limiting the spread of communicable disease and by detecting early and advanced cases of tuberculosis, many of which would have been discovered through no other source. The employee or food handler gains by an early diagnosis or knowledge of a condition present and, consequently, can resort to early treatment provided to restore him to health. The public at large benefits by the knowledge that food is being handled by individuals unable to disseminate any disease by contact.

The routine employed consists in first notifying all employees and owners of establishments handling articles of diet, to appear for physical examination on a specified day at the Department of Health, where all facilities for a proper examination are at hand. The knowledge that they will not be permitted to work at this occupation unless they possess a certificate of health acts as a stimulus to have them appear promptly. Groups are examined twice weekly. These examinations are conducted by five physicians and four nurses. Upon entering, a careful personal record of past, present, and family history of the employee is taken. He is then admitted to the second room, where clinical observations are made. Here a Widal test for typhoid is taken and cultures from nose and throat are made for diphtheria.

He is then told to remove his clothing to the waist and thus prepares for his physical test. Admitted to the clinic room, a general inspection by two physicians takes place.

The nose and throat are observed for mucous patches or other signs of contagious disease. The skin is then inspected carefully for any rash. Should a vaccination scar be absent, he is promptly vaccinated. Any suspicious sore being present, a Wassermann test is made. The genitals in males are next carefully examined for signs of gonorrhea or syphilis.

Following the general routine inspection, he is admitted to the chest clinic, where the lungs are tested by means of inspection, palpation, percussion, and auscultation. If there is discovered any suspicious pulmonary lesion, whether acute, sub-acute, or chronic, he is given a sputum box and told to return it next day.

Should the sputum be found negative for tuberculosis, he must at once discontinue work. If his condition requires immediate treatment, proper arrangements for his admission to a sanatorium are at once made. If, however, he is able to perform some sort of work, he is referred to the Federal Employment Bureau, where he may obtain occupation other than that of food handling.

Should the sputum be found negative for tuberculosis, he is notified to appear for re-examination at a future date, which is usually set for a week or so later. Then the case is carefully studied by the director of the Tuberculosis Bureau and his assistants to determine whether it is one of tuberculosis or not. It is a common occurrence that many suspicious signs found on examination of the chest have disappeared in the interval between the first and second examinations.

All clinical facilities such as temperature, pulse, and x-ray are utilized in aiding the diagnosis. Some cases are observed for weeks before a definite conclusion is determined.

In considering the applicants for examination, many who have appeared and later been rejected, never thought for an instant that there was anything wrong with them. Others, knowing that they had a tuberculous lesion, never presented themselves for examination; foreseeing positive rejection, they preferred to leave their positions rather than be discharged for tuberculosis. Another factor noticed was that, fearing rejection, many applicants de-

*Read before the New Jersey Sanitary Association, Lakewood, N. J., December 3, 1921.

nied symptoms, thus depriving the examiner of an honest history which would be of valuable aid.

Salient Points in Diagnosis

These symptoms would be most appreciated in cases of incipient tuberculosis, where the chest conditions are often hard to determine. In view of the fact that about 95 per cent of autopsies made show traces of a previous incidence of tuberculosis which may never have given any symptom during life, the difficulty is apparent when signs are slight or absent and when symptoms are denied. Again, many persons told to use sputum boxes or return for examination refused to do so and gave up their positions, assuming that the condition had been determined. These factors mask our statistics to a certain degree, so that it is impossible to obtain definite figures, and the number of positive cases of tuberculosis tabulated is limited to cases actually examined.

The following records show the results of our examinations:

From August 10 to December 1, 1920

Number examined by the Department.....	2,215
By outside physicians.....	407
Total examined	2,622
Total number examined.....	1,699
Total number suspected of tuberculosis.....	412
Suspected by outside physicians.....	4
Number of suspected tuberculous re-examined...	282
Number of suspected proved to be negative.....	198
Found to be positive tuberculosis.....	20
Found by outside physicians.....	2
Still to be re-examined by the Department.....	130
Actual cases of tuberculosis of food handlers.....	26

These twenty-six cases of tuberculosis are active and are not allowed to work as food handlers. These cases of latent tuberculosis are not considered in this paper.

Examination Should Be Compulsory

In conclusion I would say that social economy is improved by compulsory examination of food handlers. If for no other reason than the prophylactic one, i. e., of knowing that those who handle dietary products are not tuberculous, these examinations should be advocated. The Department of Health, the employer, employee, and restaurant patron are all benefited. The health of the community is without a doubt greatly safeguarded by the isolation of infected cases. Especially those in daily contact with food are aided, at the same time the public is educated to the necessity of health laws. Of equal value is the knowledge to the public that they are protected and that the food ingested has been handled without danger of contamination. Such health reforms will bring humanity to a higher standard of living and may eventually if not entirely at least limit the spread of such a dreadful disease as tuberculosis, which has spread its claws through the entire universe for many centuries.

FOOD ECONOMICS

IT IS not enough to produce food. We must also see to its storage and preservation, unless we are content ourselves to go short at some period of the seasonal cycle and to allow others to starve all the time. The Food Investigation Board has long been dealing with the problem of perishable food and its preservation, and a brief outline of its work for the year 1919-1920 is given in the Report just issued of the Department for Scientific and Industrial Research. Economical storage and transit can be determined only by knowing the physics and chemistry of foodstuffs inside and out, and every step should be taken to speed up the study of biochemistry and bio-

physics to produce results available in practice and to enable us to balance the lean years against the fat years. The projected new laboratory at Cambridge should help in this direction. Fortunately, the engineering problems of cold storage and of carrying fresh meats and fruit are being solved, and the bacteriologists are getting to know which moulds and yeasts must be carefully locked up in the Pandora box, and which are harmless enough to be let roam about. The question of transport affects the fishing industry in a peculiar degree, for the miraculous draught avails little unless it can be transported to its consumers, and small progress towards economical national housekeeping can be made so long as the glut of fish is liable to be returned to the sea which gave it or placed to rot on the land. From the land, food has to be wrested by the sweat of man's brow, and he cannot afford to forego the free offerings of the sea. The Engineering Committee of the Food Board is now busied with the construction of refrigerator wagons suited for use in this country; while the Board's Fish Preservation Committee has completed its report on the freezing of fish in time of plenty, based upon experiments carried out both at Billingsgate Market and University College, London. Progress is also recorded in the means of preserving meat, milk, and fruit, and in avoiding the moulds and spots which tend to spoil animal food while in the refrigerating chambers. Beef, it appears, may soon be preserved by freezing without altering the muscle substance; heretofore the frozen fibers in thawing lost a large part of their nutritive material in the form of hemoglobin-stained fluid. Experiments on the storage of fruit, recorded in the Report, are of peculiar interest. By the employment of certain artificial atmospheres in the storage chambers the life of the fruit may be greatly extended. The respiratory metabolism of fruit at low temperatures has been studied, and search made for the oxidizing enzymes responsible for the discoloration of certain fruits when bruised. The use of chemical preservatives is not discussed in the Report, although this method of preserving food is tempting to the producer. We may assume that the control over such preservatives in foods as boracic, salicylic, or benzoic acid, and the fluorides, to quote examples, which suggest possible injury to health, is carefully maintained under the Sale of Food and Drugs Acts. Presumably the smoke deposit on the kipper and the impregnated salt in pickled beef come outside the category of chemically treated foods. The Report as a whole, upon which this comment touches but lightly, is certainly cheering for the consumer.—*The Lancet*.

MILITARY MEDICAL CONGRESS

The Medical Corps of the Belgian Army is organizing in Brussels for the month of June, 1921, an International Congress of Military Medicine and Pharmacy, to which are invited all the doctors and pharmacists having belonged to the armies of the allied and neutral countries.

At the close of the great events which have involved the nations from 1914 to 1918, it is interesting to coordinate the work of the different medical departments, and to compare, for the purpose of reciprocal benefit, the different results obtained; it is also useful to note the advances of military medicine during the war, so as to be able to condense them into lessons for future use.

Communications to the Congress, as well as the articles and reports concerning the different questions, must be sent by the first of April, 1921, to the General Secretary of the Congress, Docteur Jules Voncken, Hôpital Militaire de Liege, Belgium. The articles must be accompanied by a brief summary.

ADVISABILITY OF ORGANIZING SPECIAL CLASSES FOR UNUSUAL CHILDREN*

BY SISTER KATHARINE, O.S.B., PH.D., DULUTH, MINN.

LAWS bearing upon the training of subnormals are so uniform or nearly so that it would be tedious to refer to more than one or two other states. We find in the General Acts of Massachusetts, approved July 1, 1919, the following provision:

"The school committee of each city and town shall within one year after the passage of this act, and annually thereafter, ascertain under regulations prescribed by the Board of Education and the directors of the commission on mental disease, the number of children three or more years retarded in mental development who are in attendance upon the public schools in the city or town or who are of school age and reside therein. At the beginning of the school year 1920 the school committee of each city or town where there are ten or more children three or more years thus retarded shall establish special classes to give such children instruction adapted to their mental attainments, under regulations prescribed by the board of education."

The state superintendent of public instruction of Wisconsin³ calls attention to the inadvisability of keeping children of varying mental levels in the same class room as follows: For several years certain schoolmen of Wisconsin have been keenly alive to the need of providing some sort of special care and education for those children who have manifested, by numerous and persistent failures, their inability to move along with their classmates in the regular school work. Perhaps no one thing contributes so much to slow progress, spiritless class recitations, and general inharmony and inefficiency as does the presence of the "dullard." Small as is his percentage in the school, he is often a considerable factor in determining the length of assignments as well as the rate at which the class work proceeds.

The Statutes of Wisconsin, 1917, Article 41,035, provide for the organization of special classes for those exceptional children. State aid is provided for districts maintaining these classes. The statute reads as follows:

Upon application by the district board of any school district embracing within its limits any village or city, or the board of education of any city, the superintendent may authorize such school district board or board of education to establish and maintain within the corporate limit of any such village or city, respectively, a special class for the instruction of exceptional persons of school age who reside in said school district or city. The courses, qualifications of teachers, and plan of organizing and maintaining such special classes shall comply with such requirements as shall be outlined by the state superintendent of public instruction. The state superintendent of public instruction shall appoint in his department a person of suitable training and experience who shall have general supervision of such classes and who shall give special attention to examining, testing, and classifying the pupils applying for admission to such special classes. . . .

Children recommended for examination for the special class in Wisconsin, and the same may be said of every other state, fell into one or more of the following classes, according to the report of the superintendent of public instruction: (1) Repeaters of two or more grades, without obvious reason other than defective mentality; (2) children showing age-grade retardation of two or more years (calling seven years normal for the first grade, eight for the second, etc.); (3) "problem cases," whose behavior or attainments caused superintendent, principal, or teacher to question the child's mentality.

Recognizing the existence of different levels of mental ability at such diverse altitudes as to make harmonious and uniform instruction practically profitless to a very large percentage of the children in our classes, would it not be well for us to consider the wisdom and expediency of organizing special classes along lines outlined in the main by the state departments, modified as need be to meet our specific needs and our large opportunities, spiritual and other. Quite recently the writer was told by a member of a community intimately associated with a Catholic school for subnormals in England that these subnormal children are finely sensitive to religious influences. May it not be that these minds, imperfectly able to reach the mediocre even in abstract reasoning processes, can be guided through sensation and imagination and the emotional activities to as high a realization of the supernatural as is vouchsafed to the more gifted? Is this not an added argument for a more humane consideration of the subnormal? The treatment of retarded children is or ought to be especially pertinent to those to whose care is given over the orphan, the deaf and dumb, and others who have a poor start in life.

No very extensive survey has been made of the mental status of children in orphanages; but from a survey made by Terman and others of an orphanage in California, the mental status of the children in that particular orphanage, at least, was more than 10 per cent below the level of a similar unselected group outside. Moreover, this was an orphanage, as Terman states, that was considerably above the culture and opportunities of a middle class home. The author is at present engaged in making a survey of an orphanage. The gross findings are not yet available, but the number of subnormals will, we think, from a preliminary survey, be slightly more than in an unselected group elsewhere, but on the other hand the brightest child the writer has had the privilege of testing was found in the one room at the orphanage where the survey has been completed.

The intellectual status of deaf children has been surveyed by Pintner, with the findings that deaf children are, as a rule, on a lower plane than are physically normal children in an unselected group.

Dependent Child a Problem Child

The dependent child is, then, a problem child. We know this. No one expects the median intelligence of children in an orphanage to be as high as is the median of the children of the well to do. At times, however, one finds in a home for dependents a child that surpasses in intelligence children of large opportunities. The question for us to consider is, are we developing to the utmost the talent each child in our particular institution has natively? The orphan's start in life is, as a rule, poor; the opportunities for advancement are limited; most likely the best friend he will ever have is the Sister in the institution that has mothered him or the good parish priest to whom he may go for guidance in difficulties after leaving the Sisters' care. At best, his lot is unenviable, and any labor we may take upon ourselves to better his condition is wisely expended.

What are we going to do? Why not make a survey of

*Part I of this article appeared in the February issue.
3. The State and the Public Schools, Cary, Madison, 1919.

the home to which we are attached to determine the number of children that are retarded a matter of two or three years? This survey will reveal also the native capacity of each child. Figure IV gives the results of such a survey made of a seventh grade. The children were each given an educational test and a mental test. They vary mentally from dull to very bright. Only one child is dull, one is very bright. The larger number of these children are normal, with a rather large percentage of bright children. The educational indices range from very poor to very good. Children whose position is between the diagonal parallel lines are in practically the same position on both axes—their educational index is about the same as their mental index. They are succeeding as well as their native ability will lead one to expect; but of the thirty-eight children here charted, only twenty-four are on the same position relatively on both axes. Five are doing slightly better work than would be reasonably expected, nine are doing poorer work than their mental index would justify. We will take, for example, the four children charted in the upper "Bright" column. We notice that their position should be two columns to the right, thus placing them in the "Good" column educationally. On the other hand, "Backward" children whose work normally would be "Poor" reach, one an "Average" and the other a "Good" rating. Probably these children are being urged unduly and there is no doubt that the nine children who are to the left of the parallel diagonal lines ought to be urged. Would it not make for more scientific and at the same time sympathetic work if each child were given a mental test and a standardized educational test so as to determine his position? No doctor leaves a general prescription for all patients who come to him. He diagnoses each case; no bridge builder constructs a bridge without knowing the carrying strength of each stick of timber and each ton of steel. The doctor has in view making the patient as nearly 100 per cent well as possible. We have in view the imparting of the great store of knowledge that is our inheritance and which, if we fail to transmit in its integrity, we become just to that extent debtors to coming generations.

But no doctor can make all patients 100 per cent well; so no teacher can turn out eighth grade graduates of the same degree of efficiency. The doctor is, as a rule, scientific in his treatment. He has only a limited list of medicines to help him out, but he does not use all of these in the same dosage for all patients. We have been trying to grind just the same amount of work and the same quality of work from each pupil; we have, on the whole, been using the same dosage of "educational medicine." We have succeeded in eliminating a very large number of children who could have learned had they been given the proper instruction and reasonable encouragement. Have we ever stopped to consider the reasons for the high educational mortality of children? Thirteen per cent of all children leave school in the fourth grade; 13 per cent in the fifth grade; 14 per cent in the sixth grade; 27 per cent in the seventh and eighth grades. In all, 67 per cent of our American children, even with added opportunities for educational advancement, leave school before finishing the eighth grade. To complete the list, 23 per cent leave after finishing the eighth grade; 10 per cent enter high school, but of these only 3 per cent graduate; 1.5 per cent go to college, and about 0.75 per cent complete a college course.⁴ It is true, economic pressure may account for a portion of this elimination, but we think that the failure to take into account differences of mental altitudes is a very large factor.

We may expect to find that from 25 to 40 per cent of the children in our classes are subnormal on an age-grade basis. If the retardation extends over two or three years, the child is likely of the dull, moron, or rather definitely feeble-minded type. This, however, is not always the case. There may be environmental causes which we can all imagine, there may be physical disability. Why not have this group of children examined by someone qualified to administer the Binet-Simon tests, or the Pintner-Patterson performance tests, in case the children are deaf or speech defectives or show great nervous instability. Arrange the record of each child on a scattered diagram in accordance with his educational and mental status.

Figure V displays the mental and the educational status of 285 children. It will be noticed here, as in Figure IV, that the children in this school vary, as they do in every other, from dull to very bright, the larger number by far being in the normal group. Seven children in this school ranked very bright; forty were bright; one hundred seventy-six normal; fifty-one backward; and four dull. It will be noticed, further, that while the majority of these children are on the same position, relatively, on the vertical and the horizontal axis, as shown by their falling between the diagonal parallel lines, a rather large number are to the right of these and a larger number to the left. The four children who are grouped at the extreme top are in the "Near Genius" class, but these are doing only "Average" work. They need urging. Two children who occupy positions to the extreme right are only "Bright" mentally, but educationally they are doing almost 100 per cent work. They are doing work which we would expect from "Very Bright" children. A diagram of this sort would give any principal, or teacher, a rather fair diagnosis of the *accomplishment* of each pupil and of the school as a whole as compared with the *possibilities* of individual pupils and of the school as a whole.

Having completed this survey, would it not be well to gather all children who are retarded a matter of two or three years or more and whose intelligence quotient is from 50 to 80 or 85 per cent of that of a normal child into one room. Retarded children can easily be managed in the first four grades with the regular classes. Their progress will be slower, as we remarked above, but there will be progress. Retarded children from the fifth grade up could well be cared for in one room. There will rarely be any retarded child who is able to do much eighth grade work. Unless the system be large, not more than fifteen or twenty children will remain in school beyond the fourth grade who are in the retarded class. Give to these retarded children a minimum of academic work, from two to three hours daily; spend another two or three hours on industrial, manual, and physical work, with a view, not of immediate productiveness, but with a view of development through sensation and perception, since the child is only meagerly capable of abstract reasoning processes.

The question here suggests itself as to what can be done in the way of pure vocational training. More especially what can be done with the retarded boy or girl between the ages of fourteen and sixteen? In some states the compulsory education law has been extended to the sixteen year level. As far as possible, it would seem that the work assigned a boy or girl, especially of the retarded type, after the age of thirteen or fourteen, at least if the child be dependent, should be such as will help him or her along towards some special type of un-

4. Goddard: Human Efficiency and Measures of Intelligence, Princeton, 1920.

skilled labor or semi-skilled labor according to the grade of intelligence, after the protection of the home has been removed. Results of surveys of answers to questionnaires seem to indicate that the attitude of these retarded children when grown to fifteen, sixteen, or over is apt to be anti-social; they are dissatisfied; they are the easy tools of unscrupulous people; through carelessness or ingratitude they increase the accident risk of employers. We cannot vouch for the truth of all these statements; but, again, does there not seem to be a great deal of truth in the generalization?

Need a Satisfactory Avocation

The boy and the girl of low grade intelligence are not able to reason out in advance the effect of an action; they are easily led; they lack stability of character. If we are to save them, we must teach them to do something that is not beyond their intellectual capacity; we must prepare them, if they are dependents, for some immediately satisfying avocation. Trabue says, "Psychological investigation of intellectual ability has revealed two classes of unhappy and inefficient persons; first, those who are employed at tasks that do not exercise the full strength of their intellectual powers and who therefore have time to think and worry about the more ambitious tasks they could do if given a chance; and on the other hand, those who are attempting tasks entirely beyond their intellectual levels and who are therefore constantly meeting failure and discouragement. Both classes of intellectual maladjustment are sources of discontent and danger." It is needless for us to remind ourselves that in such cases we must make use of such corrective means as are easily within our reach.

Before concluding this discussion of the retarded child we would like to call attention to a survey of another entire school from the third grade through the twelfth, or fourth year of high school. (Figure VI). The me-

educational median and the mental median are at the same level. In five classes the mental median is slightly lower than the educational median, or the teachers are getting slightly better work from the pupils than would be reasonably expected. In two grades, especially the 7a and 11, the educational median is high but the mental median is very much higher. Here is an opportunity for needed investigation. The results are far below the possibilities.

Second, note the high mental medians in the 8b, 9, 10, 11, and 12 grades. Elimination has taken place to such an extent that all retarded pupils have left school. Only three in every hundred pupils starting out in the first grade stay on to finish high school. We judge that 3, 7, and 6b are so-called "opportunity classes," or classes for retarded children. We notice that the mental status of 7 and 7a is twenty units apart. Looking at the array of grade medians, how, we ask, can a teacher succeed without some sort of diagnosis of the capability of the grade as a whole and of the individual pupil? How could the pupils of grade 7, for instance, work with those of 7a?

This diagram suggests that we have another class of children in our schools and in our homes. To this belong the few children who are mentally accelerated. What shall we do with the child that is decidedly above normal? Here and there, like an Alpine rose, we find a child that is a genius or "near genius"—a child that has an intelligence quotient found in one in two thousand.⁵ In the past we have endeavored for the most part to cut everyone off at the same level, compel everyone to lock-step with the system. With insufficient teaching forces, lack of funds and other handicaps, it is difficult to tell what is best to do. However, for moral reasons alone it is highly inadvisable that bright pupils be compelled to lock-step with average and mediocre children. On the other hand, there is the temptation to push bright children, or at least to "show them off" or give them encouragement

FIG. IV.—ACCELERATED CHILDREN HAVE FREE REIN FOR MENTAL DEVELOPMENT.

dian mental age for each grade is indicated on this plate by means of a black disc; the educational index is indicated by means of the circle. The median is the score above and below which there are just the same number of scores. If there are twenty-seven pupils in a class, the median score would be that made by the pupil who is fourteenth in rank. Many facts are indicated in a display of this kind. First, let us notice that in ten classes the

5. The author has under observation now a child who was given a test when barely thirteen, when she passed all the superior adult tests. This child was an orphan, in the seventh grade, and was reported as doing good work. She had made a grade every year. She is now doing the work of the first year of high school and is under observation under a class in theory of education. These students and their teacher are to help the child over difficult places and coach her in what may be necessary in the remaining work of the seventh grade and what work of the eighth grade as may be necessary. Her case will be observed with some interest, and there is a possibility that by working in the summer months she may still complete the high school work at sixteen and be qualified to teach at eighteen.

for accomplishments which lie easily within their realm. The very bright child needs simply free rein to go on as rapidly as his interests lead him. It is the dull child that needs encouragement. We would suggest, in lieu of any better arrangement, that bright children be given the assistance of a teacher to coach them several times a day in small groups so as to permit their making two grades a year or two grades in one and one-half years until they have reached the class that is at their own mental level.

Suppose a child be given a mental test at six and he is found to pass the test which the average nine year old passes. He is a superior child. He can easily, without urging, make two grades a year for three years, and by the time he is ten he will be at his mental level and can thereafter make just one grade a year and complete high school at fifteen instead of at eighteen, as would have been the case had he been held back to an age-grade level. Intellectual maladjustments discovered higher up can be condoned by a little coaching. This is true at least in a majority of cases. It is, however, difficult after the sixth grade, since so much new material is presented. The need of letting the bright child advance reasonably fast arises from the fact that if we do not let him work up to approximately maximum efficiency, we will develop an idler and a loafer at best; at worst, we will develop a wrongdoer, for the mind will keep working on something. If we do not permit of its being employed on the useful and good it will apply itself to the gross and wicked. The dull boy, on the other hand, is being constantly discouraged by his inability to perform tasks beyond his strength, tasks accomplished with ease by most of his fellows; he readily falls into the "no use trying" frame of mind. He works up to maximum perhaps for a time, but all school work, to be successful, must be glued by the mucilage of encouragement. He can get none if we are to measure him by the same standard as the bright children in the class. His work, measured even with that of normal boys, is unsuccessful. He soon loses interest. When such a boy or girl goes out into the world, he or she is accustomed to failure and looks for nothing else. If dependents, they drift from one "job" to another and, unless followed up, they will probably be found ere long in some penal institution.

Remedy in Special Classes

Let us then think about organizing special classes for mentally retarded children. Let encouragement be the watchword in such classes, encouragement based upon the promise, "Whatsoever you do to one of these my least brethren, you do also to me." Let us turn out boys and girls whose lives have not been darkened by our attempt to force upon them work beyond the capacity bestowed upon them, but brightened by the joy of accomplishment, however simple the task.

In conclusion, let us remind ourselves that there are five and one-half million children in the United States that are in the unhappy condition of being deprived, through no fault of their own, of what, humanly speaking, is the child's right, "a joyous and orthogenic childhood." They must spend their adult life in mediocrity, poverty, or dependence. At least one million of these children are in our parish schools, at least one hundred thousand are in our institutions. It is un-American to deprive any child of the possibility of procuring adequate education. These mentally subnormal children are not able to profit by the type of instruction given in the ordinary class room. Our duty seems obvious. Better mental health will be fostered by the adequate classification and the proper handling of these educational misfits.

RECONSTRUCTION THROUGH PLAY ACTIVITIES

The particular value of physical play activities in the treatment of the injured in industries is brought out in an article by Dr. Henry F. Kallenberg in the November issue of the *American Physical Education Review*. Formal gymnastics have their value, but Dr. Kallenberg emphasizes that the type of physical exercise which possesses pronounced remedial value is pre-eminently recreational. Workers injured in industries have in the past been greatly handicapped by unsatisfactory recovery, when a little more patience and persistent effort might have returned them to the workshop with a greater degree of efficiency and with a fighting chance to win out in the battle of life.

He recommends that play rooms be established in connection with convalescent wards in hospitals. Convalescent patients need mental more than physical treatment, something that will keep them from thinking about themselves and the surroundings. The article gives in detail a plan of recreational physical activities that will aid in helping to return the injured worker to his shop in as normal condition as possible.

RECONSTRUCTION HOSPITAL ORGANIZES

The rehabilitation of workers suffering from industrial injuries or occupational diseases by the application of methods developed in war work will be the exclusive field of the Reconstruction Hospital which has recently been organized by merging the Park Hospital, the De Milt Dispensary, and the Clinic for Functional Re-education, New York City. This is the first hospital of its kind in this country. The medical staff of the new hospital includes: Dr. Joseph A. Blake, who was in charge of American Red Cross Hospital No. 2, in Paris; Dr. John A. Hartwell, Dr. Victor G. Heiser, Dr. Irving S. Haynes, Dr. Charlton Wallace, Dr. Charles L. Dana, Dr. Henry Sage Dunning, Dr. John D. Kernan, and Dr. Herbert G. Reese. It is headed by Dr. W. Gilman Thompson, who is an authority on occupational disease, as well as many other medical subjects. The Board of Directors is headed by Allen Wardwell, as chairman, and includes Ralph S. Stubbs, Frank H. Jones, Bishop-elect W. T. Manning, Andrew C. Imbrie, Gerrish H. Miliken, W. Emlen Roosevelt, Chester Alexander, Robert G. Mead, Mrs. Carlos d'Heredia, G. K. B. Wade, Elwyn W. Poor, and A. W. S. Cochrane.

EYE SIGHT CONSERVATION COUNCIL

A permanent organization has recently been effected of the Eye Sight Conservation Council, which is made up of members representing various organizations devoted to health, welfare, education, science, and industrial betterment. The new organization is headed by L. W. Wallace, as president, who is president of the American Society of Industrial Engineers; Cassius D. Westcott, M.D., vice-president, Chicago, Ill., chairman of Committee on Conservation of Vision of the Council of Health and Public Instruction of the American Medical Association.

COURSE IN CHILD HYGIENE

A postgraduate child hygiene course is being given at the State Normal School in cooperation with the Bureau of Child Hygiene of the New Jersey State Department of Health on sixteen successive Fridays, beginning November 12, 1920. The detailed program may be secured from the New Jersey State Board of Health.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature
and Announcements of New Books**THE SHIBBOLETHS OF TUBERCULOSIS.** By Marcus Paterson, M.D.¹

To anyone interested in the tuberculosis problem, this book is fascinating in the extreme. The title itself fills one with curiosity which is stimulated to a still higher pitch on reading over the titles of the fifty-nine short chapters. The following are typical examples: "That Sanatoriums are no good," "That the Superintendent of a Sanatorium has a 'cushy' job," "That pine trees are necessary in the treatment of Tuberculosis," "That exertion causes Hemoptysis," "That a sea voyage is good treatment for Tuberculosis," "That good housing will eradicate Tuberculosis," etc., etc.

Throughout the entire book the very vivid personality of Dr. Paterson himself is strikingly in evidence as is likewise his firm belief in the value of the opsonic index as taught by Sir Almroth Wright and in auto-inoculation as carried on by Dr. Paterson himself.

There are several statements made by Dr. Paterson which will not bear analysis but which are none the less interesting reading. For instance, he devotes two or three chapters to prove that climate has no special value in the treatment of tuberculosis and to support this argument quotes figures showing that the death rate for tuberculosis is higher in Colorado and California than it is in many more crowded parts of this country and of England. Dr. Paterson knows, and if he does not know he certainly should know, that the cause for this increased death rate in the two above mentioned states is to be found in the great influx of advanced and dying consumptives who are sent there in the vain hope of a cure. It is quite foolish of him, or indeed of anyone else, to maintain that climate has no value in the treatment of tuberculosis. Because, for instance, the incidence and death rate of tuberculosis in Egypt is high, doubtless due to the faulty hygiene and methods of living of the natives, does not prove in the slightest that the dry climate of Egypt is not good for certain cases of consumption.

He devotes a chapter to proving that hemoptysis is never caused by exertion. To those of us who during the past winter have been able in our own minds at least to explain satisfactorily numerous pulmonary hemorrhages to unwise exertion on the part of patients such as the shoveling of snow or coal, his argument that exertion is no factor in the causing of such hemorrhages is not impressive. If he stated that in active ulcerating tuberculosis where the process is steadily advancing and in so doing erodes a blood vessel exertion or exercise is a factor of no moment, we would all agree with him, but he does not state this although he doubtless believes it.

He is evidently a firm believer in blood inoculations into guinea pigs as a diagnostic measure. This has practically been given up in this country. As above stated, his infinite faith in the treatment of tuberculosis by auto-in-

oculation is very evident and he holds up to some ridicule a certain very prominent American physician, an authority on tuberculosis, who is an equally strong advocate of rest and opposes auto-inoculation in any form and graduated exercises as carried on by Paterson. The truth probably lies mid-way between the two extremes. He draws the distinction, which is a most important one for those of us who live in New England to remember, that pure air does not necessarily mean cold air.

The book is full of epigrams and aphorisms. The following are good examples: "Changing a man's work is not treatment"; "It is not the diet that matters so much as the inducing the patient to partake of it"; "Fatness does not increase the specific resistance in tuberculosis"; "It is not the buildings of a sanatorium that matter, *but the man in charge of them*"; "Many homes for tuberculosis exist, but few sanatoriums."

It is easy to go through this book and find many points with which to disagree. It would be difficult, however, to find a book which on the whole would be more refreshing and more stimulating and a more welcome addition on this subject to our literature than this book.

J. B. H.

TEXT BOOK OF NERVOUS DISEASES. For the Use of Students, and Practitioners of Medicine. By Charles L. Dana, A.M., M.D., LL.D.²

This volume is the ninth edition of a textbook which first appeared twenty-eight years ago. The author states that the successive volumes present in a measure the advancement of neurology during that period. In this volume material bearing upon the important contributions resulting from the observations in the great war, have been added. A chapter has been added on endemic encephalitis and on psychology in its dynamic, descriptive, and physiological phases. No attempt is made to present the subject matter in accordance with various evolutionary "levels," and little space is given to endocrinology. Inasmuch as this volume is a textbook, it seems to the reviewer that this is a very wise procedure, as otherwise much controversial matter would have to be included. The volume represents a concise and comprehensive exposition of diseases of the nervous system, clearly presented, well illustrated, and especially adapted for teaching purposes. Of particular interest to the reviewer was the following paragraph in the preface: "I would add as showing a present somewhat hypomanic trend that more than twenty books have been recently published on psycho-analysis, about one-fifth being by lay writers. All these may be found in a general book store on counters much patronized by women." Whatever our individual views may be relative to psycho-analysis, until the subject has passed the controversial point, it would seem better to deal with the matter conservatively when presented in textbooks.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

A TEXTBOOK OF DERMATOLOGY. By J. Darier, physician to the Hospital Saint-Louis. Authorized translation from the second French edition.³

As anticipated, Pollitzer's translation of Darier's book is a valuable addition to the textbooks on dermatology. The illustrations are excellent and numerous. The chapters on tuberculosis and syphilis are extraordinarily good, while the one on treatment is not excelled by that of any other publication. The book is particularly valuable to the junior and senior medical student. There seems, however, to be scant attention paid to the literature of dermatology from other countries. Reference to many splendid contributions from American and other dermatologists has been omitted. The book should be included in every modern medical library.

J. S. EISENSTAEDT.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD PHYSIOLOGY. Pure and Applied. By W. M. Feldman, M.B., B.S., (Lond.)⁴

One seldom finds a book that contains as much information as the present volume. The author has gathered a wealth of knowledge which he embodies in a small volume of 694 pages. He presents the reader not only with a great deal of data on the subject of ante-natal and post-natal physiology, but he discusses at length many allied subjects, such as theories of heredity, mechanics of development, and physiology of fertilization, the whole theses displaying a great deal of erudition and profound scholarship.

If there is any criticism on this excellent volume it is in the direction of the mathematical insertions scattered throughout the book. In some places the author devoted the greater part of a chapter to the presentation of mathematical formulas that detract from the interest of the book. He erred in the same direction in a previous publication, "The Jewish Child," a most valuable contribution in every other respect.

As a whole, however, one may find in the "Principles of Ante-Natal and Post-Natal Physiology" a great deal of interesting information. The volume would make a valuable addition to the library of every physician and scientist. Child care constitutes a highly important field in preventive medicine and such studies as this give it the proper scientific background.

CLINICAL OPHTHALMOLOGY FOR THE GENERAL PRACTITIONER. By A. Maitland Ramsay, M.D. With a foreword by Sir James Mackenzie, M.D., F.R.S.⁵

Mackenzie's belief that textbooks of the classic type are failures because of their foundation on pathology is responsible for this "specialty" book by a specialist who was in his earlier days a general practitioner. The book was reviewed by an internist who, of course, is in no position to pass judgment on the purely special side of it; but from his point of view it is a valuable volume. The general practitioner, even the more purely specialistic internist, requires an interpretation of symptoms and signs from a diagnostic and therapeutic point of view which he will be able to correlate with symptoms and signs in other organs. This has always been difficult to achieve; mainly, we believe, because books are written *for* specialists as well as *by* them. Ramsay's book seems to "hit the nail on the head"; even the difficult field of ophthalmoscopy is treated in a manner easily understandable by the average practitioner.

We can commend this book highly and trust that more of the same caliber will be forthcoming in the series promised by the publishers.

THE NATION'S HEALTH

WITH the May issue the name of this magazine will be changed from MODERN MEDICINE to the NATION'S HEALTH. This is being done to make the title more clearly descriptive of the present scope and the new and greatly enlarged service of the magazine in health promotion and conservation.

The change is one which has been under consideration for some time. It is the final step in the development of a magazine which we confidently expect will be of distinctive service to those who are in positions of responsibility for the nation's greatest asset, the health of its citizens.

The change of name and the broadening of its field of endeavor complete the transformation of the *Interstate Medical Journal*, the predecessor of MODERN MEDICINE, from a publication devoted to clinical medicine, to a health magazine of broad national service—a magazine devoted to community, industrial, and institutional health problems.

The NATION'S HEALTH will continue those features which have proved most interesting and serviceable to the readers of MODERN MEDICINE, but will cover the subjects treated more completely, and in addition inaugurate other features which are important in the new and wider field.

THE SCOPE OF THE NATION'S HEALTH

THE NATION'S HEALTH will be devoted to the field of community health, with special reference to industrial and institutional health problems. The health of groups will be the central theme, whether the group be the workers in a plant, the students in schools or institutions, or the citizens of the community.

Industrial health and efficiency will receive increased attention and special emphasis will be placed upon the conditions in industry which make or mar the health of workers. The problems of industrial medicine will receive scientific attention with the assistance of the board of editors of the American Association of Industrial Physicians and Surgeons. Industrial efficiency, the improvement of working conditions, plant morale, the promotion of physical fitness, ventilation, illumination, and sanitary equipment will receive special consideration.

Community health, including organized health activities, public health nursing, and sanitation in its broad aspects, will be continued with emphasis upon the practical methods for the prevention of disease and the promotion of health and physical efficiency as worked out by experience throughout the country. Problems of infant welfare and child health, particularly the health of school children, will be specially emphasized.

Institutional health, including physical care, health service, and medical attention in institutions, boarding schools, military schools, and colleges, will be given the consideration which the importance of the health problems in the thousands of institutions deserves. The health and safety of summer camps and labor camps will be given their proper place in the program of promoting better health.

The organization of health workers, including the physicians, sanitarians, health officers, industrial managers and experts, public health nurses, and welfare workers, will receive an increased degree of attention in the new magazine. Group organization by physicians for private practice, public health enterprises, diagnostic clinics, health centers, and health education of groups, are some

of the subjects upon which the experience of the country will be mobilized. Curative medicine will be left primarily to the excellent journals which have always served the clinician.

The magnitude of the health service to the groups mentioned becomes apparent in consideration of the following facts: More than forty million workers are engaged in gainful employment. The majority of these work in groups of fifty or more, each group constituting a unit for industrial health service. There are twenty million children in the schools who should come within the range of health organization. There are more than five thousand private schools, institutions, and homes for the aged in which group health service is of prime importance. There are many thousands of summer camps and workers' camps where life and health are constantly endangered through the crudity of living arrangements.

All of these groups offer opportunities for the promotion of physical well being and working power as well as for protection against disease. We believe that the most effective work for the present time can be done with groups, and to that end the work of the magazine will be devoted.

MENTAL DEFECTS AND CRIME

THOSE who occupy themselves with attempts to discern in the vagaries of the human mind a basis for the determination of the laws governing mental reactions are continually reminding us that there is no hard and fast boundary between mental defect and mental efficiency. The responses of high grade defectives, they claim, average quite favorably with those exhibited by people of sound mind but whose intelligence is of low grade, and under habitual, smooth-running conditions comparison may not reveal the inadequacy of the defective.

Even unsocial reactions may not safely be taken as an index of defect, for criminologists urge that all human beings are potential criminals, that whatever the degree of intelligence, a crisis is conceivable in which all organized inhibitions would fail to control and a so-called criminal reaction would result. The word crime itself is a variable, and gets its definition from the contemporary social conscience.

The growing mass of literature devoted to the study of criminals themselves rather than to that of crime and the problem of punishment, and the tendency to regard offense in the abstract in an effort to find the category to which the offender belongs, show the effort to evolve a science of criminology, an outcome which is hardly to be expected inasmuch as no exhaustive study of criminals in the mass is likely to be made and

because it is impracticable to ascertain the facts of the early history even of sane criminals.

Such studies as are made by Healy in his work on "The Individual Delinquent" merely emphasize the importance of individual study. They are not sufficiently extensive for particularly valuable generalizations. The work of Charles Goring on "The English Convict" brings out a "high association between crime and insanity," and manifestly the handling of criminals would be greatly simplified if the rather large percentage of all offenders easily recognizable as insane were certified and sent to asylums instead of to prisons. Mental defect in general, however, according to Sir Bryan Donkin,¹ whose review forms the basis of this comment, offers far greater practical difficulties. High grade defectives with no remarkable lack of intelligence may "show such constant and patent defects of conduct (indicating disorder in the sphere of the emotions or of morals) as to render them dangerous members of society." A rating, therefore, is not to be assumed on intelligence capacity, but the degree of defect is to be considered with the correlated conduct.

In the defective, self-regarding conduct is preponderant over social conduct. Orderly control by acquired motives is impossible to him. Such offenders should be amenable to preventive detention. Better still would be such observation and records from school age on of manifestly potential criminals as would form an authoritative basis for their classification. Where there is educability, social responsibility attaches, not merely for the provision of restraining care but for such training as will tend to develop useful habits. The human mind is a "social product" and the environment in which a given mind develops may be as much at fault as the constitutional defect.

The communication of Sir Bryan Donkin deals with the problems of definition under the English Mental Deficiency Act. Not much help as to classifications is afforded by our present knowledge of cerebral and other organic manifestations of mental disorders. Much of the research by the biometric method is open to dispute and the assumption of a "criminal diathesis" is obscure. Active measures toward reclaiming the criminal are necessary, and a careful study of the individual offender should influence far more than it does at present the sentences awarded in law." In the opinion of Donkin no judge should pronounce any imprisonment sentence unless he is personally acquainted by visiting prisons with the actual nature of the terms of imprisonment entailed by his sentences.

PHASES OF THE AMERICAN RED CROSS IN EUROPE

BY THEODORE C. MERRILL, M.D., AMERICAN RED CROSS, PARIS

THE life of the American Red Cross in Europe has passed thus far through three stages which are fairly distinct, although they overlap to a certain degree. The organization now appears to be entering upon a fourth period.

The first stage was that of military medical and canteen service, hospital construction and aid, camp and relief activity, and refugee assistance—all of which were accompanied by fundamental health work which afforded not only a material contribution, but which was of a welfare and educational character. The type of such educational enterprise is represented by the tuberculosis and infant welfare campaigns conducted in France. These campaigns were analogues of the work constituting a major portion of succeeding periods. The more military and general service was instituted in many countries, namely, Great Britain, Belgium, Germany, Austria-Hungary, the Balkan states, Greece, Italy, West Russia and the Baltic states, northern and southern Russia, and Switzerland. It has necessarily existed in other countries to which special reference will be made, but in the periods following the first there has naturally been a decline in the military nature of American Red Cross functions, except as recently revived in Poland. American Red Cross help in the Central Powers during and immediately after the war was demanded, particularly in connection with prison camps and with the repatriation of prisoners released; there were instances of large numbers of prisoners being set free utterly without food and facing no prospect except starvation.

The second stage extends from the signing of the armistice to the spring of 1919. This period is represented by canteen, home communication, and similar services conducted for the benefit of large numbers of American soldiers awaiting transportation home. Military atmosphere continued with the Army of Occupation in the Rhine region. During this period the greater part of the French public health line was brought to a close.

Efforts Devoted to Welfare

The third phase is the one in which we are most interested just now. It began in the spring of 1919 and extends to the first of October, 1920. This epoch is devoted to welfare, education, medical and surgical demonstration, refugee aid, typhus control and to national encouragement whose object has been to educate, so far as pos-

sible, various of the European peoples to a proper appreciation of health values. General utility has constituted a substratum of the American Red Cross; there has been a recrudescence of war relief in Poland; but the *pièce de résistance* of this period has been the demonstration afforded populations in Serbia, Poland, Montenegro, Roumania, and Albania. Of notable extent and value has also been the program in West Russia and the Baltic states, Italy, Greece, the Crimea, Constantinople, Budapest, and Vienna.

The fourth period is that now confronting the American Red Cross. It is one in which the American people at home are deeply and essentially interested, however insufficiently the importance of this interest may be understood in some quarters and by some of our people. In order to throw a little light upon it from the medical point of view, and for the purpose of showing how inevitable is the necessity for continuing the American Red Cross in Europe, the effort is here made to present something of a review of the third stage or epoch of what we may call the European American Red Cross. After offering this review, we may again advert very briefly to the impending fourth cycle in the era of evolution which has been unfolding most impressively since the collapse of the Central Powers.

When it became necessary to undertake war and post-war service in Europe, five types of activity were prescribed for the American Red Cross: (1) Emergency work for all ages and classes. (2) Health and sanitary counsel for country and locality. (3) Demonstration of methods for the

The American Hospital at Niksic, Montenegro.

care of children, ante- and post-natal. (4) Training of native workers to become nurses, health visitors, etc. (5) Care of orphans, especially war orphans.

Since our attention is directed chiefly to the third stage of European endeavor, we shall allow these five types of enterprise to illuminate the historical period whose close is imminent.

The regular morning line-up at the American Red Cross Dispensary, Kolachin, Montenegro.

Flood, fire, famine, disease, cosmic forces, and anything else that our transportation companies might class as acts of God contain an appeal which is irresistible. When the human race brings down calamity upon itself, the call for aid provokes response which is no less ready and sincere than the answer in the absence of human responsibility. In this third period the principal emergencies have been those of famine, cold, and disease; which, in turn, have resulted from the war and must be attributed to human deficiency. With these emergencies, and almost as important as they, must be associated mutilations which cripple the bodies and impair the economic utility of the unfortunates who sustain them.

Emergency Speaks Imperatively

The main medical emergency of this epoch promised to be that of epidemics. Just at the close of the period, however, we must include the emergency constituted by the need for first aid, surgical dressings, and surgery as created by the Bolshevik advance in Poland.

Epidemics have been those of typhus and cholera. Typhus was widely distributed in Poland and Serbia during the past winter. It threatened to sweep through the Baltic states, but was arrested by the American Red Cross as directed by Colonel E. W. Ryan, Commissioner to West Russia.

The measures adopted were exaction of cleanliness and enforcement of quarantine and delousing regulations. The governments of Latvia, Estonia, Finland, and Lithuania recognized their inability, and it was their appeal to the American Red Cross which resulted in the abolition of the disease. From February 25 to April 13, 1920, vigorous regulation was enforced in seven cities; 4,950 typhus cases were supervised and guarded.

Causes of the spread, as given by the Commissioner, were: Entire lack of hospital discipline; overcrowding of patients; and general filth and laziness.

The statement is made by physicians returning from the Baltic states that there is no excuse for a recurrence of typhus during the coming winter. However, the European scene may quickly change and nobody can surely predict what will happen. At present American Red Cross personnel are on hand in seventeen cities within the Baltic states.

Cholera, as occurring in the Crimea, included 3,122 cases cared for, with 1,204 deaths.

Up to the time of the unfortunate Polish advance into Kiev and the invasion of Poland by the Bolshevik army, laboratory, hospital and orphanage work was considerable; and the typhus and refugee situation had been greatly ameliorated. All such endeavor was arrested by the military operations of last spring. American Red Cross reverted to first aid and surgical relief of the military nature which is primordial in Red Cross history. Five railway cars were equipped with supplies and personnel and attached to the Polish army. Statement is made by the Commissioner to Poland that "but for the cars, thousands of wounded would have had no treatment for a long time. Some of the wounded arriving at Brescz Litovsk early in the offensive had not had their wounds dressed for eight days." Figures reported for the cars show that cases treated between July 23 and August 31, 1920, were: medical, 380; surgical, 4,642. This is an understatement, as the cars were directed by the Poles and some of the work done by the American Red Cross does not appear in American records.

So much for emergency service in the American Red Cross third phase.

Sanitary, medical and health help for towns and nations, as a mass effect, has been most substantial in in Serbia, Poland, Montenegro, and Albania. First of all, has it been necessary to handle disease conditions, but teaching of the backward people has been maintained along with treatment of cases. The treatment has been medical and sur-

An heir of the clinic at Elbasan, Albania.

gical, mostly of the general type, but with occasional chance for special work. Hospitals, dispensaries, orphanages, and clinics have been the media of expression. For a long time before the war there was no hygiene, sanitation, or public health in these countries which was actively practised by the mass of the people. The war added to previously existing evils and then took the lid off so that all the world might see. Teaching by the American Red Cross and other organizations is believed to have provided the "first steps in national hygiene" for nations which, during centuries, have been victims of indolence, ignorance, oppression, and wholesale graft. The actual effect of the relatively brief service of these organizations is conjectural. Some of the field personnel report a perceptible impulse toward improvement. Others are skeptical. When one considers the discouragements which attend all public health effort at home, but also remembers the progress that unmistakably accrues, he need not necessarily feel that the labor in Europe has been lost.

The program has been about the same in Serbia, Montenegro, and Albania, according to the essentials just mentioned. Another aspect of Red Cross work has been subordinate in these three countries but has given a color of its own to Poland. This character is that of aid and cooperation as manifested in hospitals and other institutions directed not by the American Red Cross, but by native physicians and surgeons. Few hospitals in Poland have been administered by the American Red Cross; here the line has been in the direction of contributions of food, clothing, and equipment, the American medical personnel working under native directors. This is one of the reasons explaining the limited medical figures which the Red Cross can show for Poland, speaking in the statistical sense. The effort is reflected

in food, clothing, and supply records; but some of the more strictly medical detail must be sought in records made by the Poles, and some is lacking for reasons mentioned below.

The subjoined Charts I, II, III, IV, and V illustrate the medical relations of European *pièce de résistance*. Those for Serbia, Albania, and Montenegro speak for

themselves, being based on cases actually reported by hospitals, dispensaries, and clinics. The same is true of the surgical and dental graphs shown on the Polish chart, their small number being due

The American Red Cross dentist in Belgrade.

chiefly to two factors, namely, the emergency and general relief character of the Polish activity and the recurring military operations, which interrupted the developing program. The medical graph on the chart for Poland includes general medical and surgical relief as well as treated cases.

The charts refer to February, March, April, and May, 1920. It is regretted that accurate report has not been possible earlier. The fact is partially explained by reasons just mentioned; other factors are failure to appreciate the value of careful record, lack of time to devote to "paper work," defective transportation, interruptions, delays, many of which could not for a long time be eliminated in the face of existing pressure, demand, and lack of clerical service.

Limited as it is to medical and surgical relations, and these, too, being restricted to the professional side, this résumé must remain as an incomplete portrayal unless supplemented by similar summaries which the supply and nursing services can alone compile. A trilogy of the nursing, supply, and medical lines of the American Red Cross in Europe, presented in one popular or semi-popular article, does not, perhaps cannot, exist; official reports and fundamental figures repose in the archives against a time when leisure and personnel may be found to transform them into living pictures.

Typhus is major, cholera coming next in importance. Typhus is at a maximum in winter and at a minimum in summer, the periods being reversed for cholera. The influence of summer on any gastro-intestinal disease is well understood; the typhus summer minimum is not due essentially to season, but is an indirect and negative result, the heavy winter incidence depending on the crowd-

A case of noma seen in Serbia. Cases resembling noma sometimes prove to be anthrax.

Children taking the sun cure at the tuberculosis hospital in Vienna, aided by medical supplies from the American Red Cross.

ing and heavier clothing consequent on cold weather, the life of the body louse being thereby favored. During the winter typhus—especially in Poland—tuberculosis, influenza, pneumonia, bronchitis, tonsillitis, and the exanthemata are most numerous. There is always much eye disease—especially conjunctivitis; not much trachoma—abundant skin disease, and considerable otitis media. On the approach of spring and summer, malaria and dysentery appear. In the southern parts of central Europe estivo-autumnal malaria, and the other varieties, are extensive and serious. We have not had positive diagnoses of amebic dysentery. "Sandfly," or pappataci fever, abounds.¹ Typhoid, tetanus, dengue, and relapsing fever vary in frequency; tetanus is largely avoided by prophylaxis. Bone and gland tuberculosis has occupied much hospital and dispensary attention; there is plenty of pulmonary tuberculosis, but space and personnel are inadequate for intensive treatment by the Red Cross and practically no sanatoriums exist, so that such cases are largely neglected.

The beginnings of oral hygiene in France.

1. Castellani and Chalmers: *Manual of Tropical Medicine*.

Southern Europe is marshy and mosquitoes breed freely. Food is prepared and handled in shop or home with no reference to protection or cleanliness. Soil pollution being uncontrolled, intestinal parasites of all kinds are harbored alike by young and old. Scabies is a mere commonplace. Many inoperable cancer cases have been reported.

Dental service is highly appreciated, there being few competent native dentists. The same is true of surgeons. Theoretically, there are some excellent surgeons, but they are not capable in the practical sense. A valuable Red Cross contribution in Serbia consisted of an artificial limb shop, operated as an object lesson, as well as to supply a serious lack. It developed a type of apparatus especially useful for local conditions and in relation to knee disarticulation. A store of wood was accumulated to be seasoned for later use. Nearly one thousand cases needing artificial limbs were supplied by this shop between April, 1919, and June, 1920, when it was turned over to the Serbian government.

Child Hygiene in Practice

Considerable theoretical hygiene for infants and children was taught before the war, but throughout Europe effective practice of the sort has largely lapsed into oblivion. The scene revealed by the war causes one to doubt whether child hygiene was, after all, anything generally adopted. Recent work by the English, French, and Italians reflects great excellence, keen individual interest, and a strong reaction to the unrivaled stimulus imparted by the grave results of the war. All European governments are rising to meet the population crisis and encourage every influence tending to preservation and development of the young.

Children have constituted a large proportion of the patients cared for in American Red Cross hospitals and dispensaries. Home visits by the medical and nurse personnel, addresses to mothers, and demonstrations in dispensaries and clinics have been inseparable from the program. Pediatric teaching has been especially prominent in France, Italy, Roumania, and Greece. In France most of the child activity has been situated in a portion of the devastated area toward the north; it has included the recuperation of poorly nourished and pre-tuberculous children from the vicinity of the former front, a number of them having been placed in French homes on the coast and in the South. Child centers were established in Italy; American Red Cross personnel no longer remains there, but the Italians are carrying on the ideas imparted to them and their

pediatric leaders have plenty of originality of their own. In Greece child centers persist at Athens, Canea, Patras, and on an island of the Cyclades group. A large dispensary is continued at Salonica. The effort is always to enable the native people to handle their own problems.

Roumania has enjoyed special attention in the child problem, some half dozen stations having been established there. The Red Cross has withdrawn, but another—British—organization will probably continue. Study of small groups of children is being made in south Russia. In Czecho-Slovakia a nurses' program has been instituted by the new state, two able native women having been sent to America for study designed to fit them for directing a national nurses' movement in their country. The new development will include special attention to the needs of the youth, for exercise and athletics for girls and women, boys, and men are being especially encouraged by large associations, the Sokols.

In Montenegro a group of 210 school children, about equally divided between boys and girls, was inspected by a native physician, Dr. Matanovich, and classed in four age groups, the diseases most noticeable being indicated in the table; the diseases are mentioned in the order of frequency:

TABLE I.—TABULATION OF AN EXAMINATION BY A NATIVE PHYSICIAN OF 210 CHILDREN. AGE-GROUPS ARE INDICATED, AND THE DISEASES ARE MENTIONED IN THE ORDER OF THEIR FREQUENCY.

Group 1 7-8 years	Group 2 9-10 years	Group 3 10-11 years	Group 4 11-12 years
Tonsillitis Anemia Cervical adenitis Scabies	Anemia Tuberculosis (pulmonary) Tonsillitis Malaria	Anemia Tonsillitis Cervical adenitis Bronchitis Malaria Myopia Scabies	Anemia Tonsillitis Cervical adenitis Tuberculosis (pulmonary)

An adverse influence not infrequently encountered is the tendency manifested by the native mothers—and not alone mothers—to attend clinics, listen to addresses and otherwise meet the Red Cross educational effort solely because they expect to receive donations of food or clothing. The idea of education for education's sake, and for assuring future advantage to the individual and community, is not readily grasped. The American Red Cross has continually to guard against permitting educational activity to degenerate into a mere charitable distribution of goods and chattels.

Something of this departure has been indicated in speaking of Czecho-Slovakia. In Italy and Greece there are nuclei of native nursing personnel. The idea is taking root in Roumania. A powerful counter-influence, which must usually be combated, is the prejudice existing almost universally in central Europe against the profession

CHART I.—THIS CHART SHOWS THE MEDICAL, SURGICAL, AND DENTAL SERVICE RENDERED BY THE AMERICAN RED CROSS IN SIBERIA IN FEBRUARY, MARCH, APRIL, AND MAY, 1920, AS REPORTED TO THE MEDICAL BUREAU, PARIS.

TOTALS CHARTED ABOVE •

MEDICAL CASES	56,082	Number of Hospitals	9

of nursing, which is considered degrading and unworthy the attention of capable, important, and educated (*sic*) persons. However, it has been found possible to interest women and girls of the middle and lower classes, selection being made of the intellectually capable among a number none of whom have received much education. No nurses' salaries worthy of the name are yet provided.

In several cases, education has extended to physicians and surgeons. A very competent physician (general medicine and pediatrics) has been developed in Montenegro and another in Albania; also in Albania, a surgeon has been made very capable by faithful effort on the part of the surgeon supplied by the American Red Cross.

This hospital in Athens, Greece, is aided by the American Red Cross.

Orphanages have naturally co-existed with hospitals, dispensaries, homes for the aged and similar institutions in all European countries. They have struggled along under the serious difficulties of insufficient food, fuel, and clothing. The American Red Cross has aided these institutions by supplying deficiencies and caring for the sick. In some of the institutions, isolation of infectious cases was secured only after long and persistent effort, insistence, and persuasion, directed to official influences which controlled the allocation of buildings and rooms, as well as to crude ideas which had never valued sanitation or hygiene. In Serbia this difficulty was embryonically combated by a policy, local and limited, contemplating the placing of orphans in good homes rather than in formal institutions. To be effective, such a policy would need a time longer than that yet available to the American Red Cross.

In Poland, a large orphanage, containing about seven hundred children, was situated at Bialystok; it had to be moved from under the oncoming Bolsheviks and was transported across Poland. In Albania there was one Red Cross orphanage, in Montenegro four, and in Serbia two. Help has been extended to hundreds of orphanages; great distress in orphanages at Budapest, Vienna, and Constantinople has been ameliorated by contribution of supplies. Czecho-Slovakia and Russia have been among the countries thus benefited. Such work constitutes a large and important function of the Junior Red Cross.

The New Era of Service in Europe

Although there has been a notable reduction in the overseas personnel, the duties of the organization in Europe have not ceased. The American Red Cross will maintain a foothold in several countries engaged in that most valuable, because fundamental, endeavor—the promotion of

interests of the child. Poland, Montenegro, and Albania will be represented in this effort, and Czecho-Slovakia will receive some attention.

Russia, also, is beginning to loom into the Red Cross horizon, but is naturally not yet an objective, except as already indicated. There is no question as to the terrible nature of conditions in Russia and the need for relief there; but the political atmosphere does not yet warrant a Red Cross response to the prayers which reach it from many Russian places. Russian refugees, scattered widely from the Crimea, are being assisted along the shores of the Adriatic, in Serbia and about Gallipoli and Constantinople.

The American Red Cross cannot do less than remain in Europe while there is urgent need for

it, from the humanitarian standpoint in relation to the interested countries. It constitutes a healthy and important stabilizing force amid the whirl of conditions accompanying rehabilitation; and its stay is required by reason of public health considerations.

The world has a vital interest in the prevention of spread all over it of epidemic disease from the active European centers. Against some of the infectious diseases there are more or less effective preventives, as in the case of smallpox, malaria,

CHART IV.—AMERICAN RED CROSS MEDICAL, SURGICAL, AND DENTAL SERVICE IN POLAND FOR FEBRUARY, MARCH, APRIL, AND MAY, 1920.

TOTALS CHARTED ABOVE

MEDICAL CASES	74,900	Number of Hospitals	3
SURGICAL	"	1,645	Orphanages 1
DENTAL	"	4,050	
TOTAL	80,595		

STATISTICS PREPARED BY DR. T. C. MERRILL A. R. C.

syphilis, diphtheria, tetanus, and typhoid; or at least there is supposedly adequate treatment. For some of these diseases, such prophylaxis and treatment may be employed on the home European

field or in countries receiving persons so infected. Other affections, however, are not readily amenable to the specific method of control, and emigration of carriers must be prevented.

CHART V.—THE AMERICAN RED CROSS ACTIVITIES SHOWN IN THIS CHART ARE BASED ON CASES ACTUALLY REPORTED FROM HOSPITALS, DISPENSARIES, AND CLINICS.

AN AVERAGE RED CROSS DAY IN CENTRAL EUROPE

- The small number of surgical cases in Poland was due to political conditions.
 - Including general medical relief, aid to hospitals, dispensaries and orphanages and distribution of medical supplies.
- Facts represented are based on field reports for February, March, April and May 1920.

STATISTICS PREPARED BY DR. T. C. MERRILL A. R. C.

Fundamental Interests

The child now comes into the limelight as the most important asset to Europe. Effort is being made to find methods of cooperating with governments which are especially interested in their children. It is hoped that American sympathy may be a support during the coming months, not only in material things, but as an influence welcome for the sake of considerations not directly material.

The guiding principle of the American Red Cross will be: help the native peoples to use their own methods in helping their own child life. There is no intention to impose Americanism upon other ethnic groups.

To America, then, the American Red Cross looks for backing and wholehearted interest in its European plans. The organization is grateful to the American public, whose spirit it reflects, for approval of enterprises devoted to infancy and childhood, and, through them, to the home. It is upon the home, the child, and the infant that the Red Cross attention will be concentrated during the year 1921. Better homes in Europe will mean, at a later time, better homes in America and citizens impregnably fortified to continue, firmly and honorably, the best that there is in the institutions we love so deeply in the land of Uncle Sam.

REQUIRE MEDICAL AID FOR CHILDREN

Employers of non-medical healers were threatened with prosecution for manslaughter or neglect, on proof of failure to provide proper medical attendance for their children, by Thomas Lee Woolwine, district attorney of Los Angeles County, is a recent letter to Dr. Rea Smith, president of the Los Angeles County Medical Society.

The letter asked the cooperation of all members of the medical organization in reporting cases of alleged violation of state laws covering the care of children as a "work of mercy and justice."

It should be understood, the letter said, that the fanaticism indulged in by such practitioners, by whatever name they may be called, could not be urged by any parent as a lawful excuse for failure to furnish necessary medical attendance for children in case of serious illness.

Further, I am satisfied that, in case death should result from such omission, such parent would be guilty of manslaughter.

It is, of course, well known to members of your profession that parents suffering fanaticism and delusions to allow their babes and children to die of malignant and contagious diseases, feloniously refusing to provide that medical aid required by the statutes of California.

The number of helpless infants who have been robbed of life and allowed to die under such circumstances since this peculiarly dangerous and inhuman fanaticism has been promulgated, has undoubtedly reached appalling proportions in the United States.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER

BY FRANK J. OSBORNE, EXECUTIVE SECRETARY, NEW YORK CITY

UP TO July, 1919, 76,433 American soldiers were killed or died of wounds or disease in the Great War. During the same two years it is estimated that at least 180,000 people died of cancer in the United States. Stated in another way, there is now an average of ten deaths from this disease in this country each hour, or one every six minutes. This high mortality from cancer is not new, though it is increasing each year. Many years ago it was noticed that this disease was becoming more and more prevalent, not only in this country but in European and other countries as well.

As far back as 1904 the American Medical Association appointed a committee which reported in favor of educational work regarding cancer. This resulted in the formation of the Council on Health and Public Instruction through which the largest American organization of physicians became active in the education of the public regarding subjects of health, and has since prepared and distributed many valuable pamphlets on cancer.

The surgeons of the country also realized the great significance of cancer as a cause of death and appreciated also by personal experience that

thousands of lives could be saved if they could persuade the patients to come earlier for treatment. The Clinical Congress of Surgeons of North America, therefore, designated a cancer campaign committee which in 1912 secured the publication of a number of popular articles in widely read magazines such as the *Ladies' Home Journal*, *McClure's*, and *Collier's Weekly*.

Several things are essential if the general public is not to remain unable to assume the initiative and to be unreasonably dependent upon the fortuitous advice in matters pertaining to maintenance of health.

The habit of examining and criticising results must be developed if any independent judgment is to be safely risked as to the value of any given health measure or as to the efficacy of any preventive work.

General health propaganda should offer universal information as to preventive measures in the more common maladies, should protect the masses, and the habit of taking a periodic health inventory should be the safeguard of the individual.

In the following year the American Society for the Control of Cancer was organized to attack the problem in a uniform manner on a national scale, the project growing out of the earlier attempts to educate the public, the specific impulse being an outgrowth from the work and report of a special committee of the American Gynecological Society, a group of physicians whose lot it is to treat diseases of women. Pre-

vious to the meeting at which this report was rendered at Washington in 1913, held in connection with the terminal Congress of American Physicians and Surgeons, the Committee had conferred with a number of experienced health workers and interested laymen. A definite need was demonstrated for such an organization, since none of the other national public health agencies was covering this field, and funds were guaranteed the Committee by five philanthropic laymen, provided the undertaking should meet the approval and support of the medical profession.

Immediately following the report of this special committee, delegates were appointed from all the special medical societies associated with the Congress of Physicians and Surgeons and the new Society was launched under their direct auspices

within two weeks thereafter. An office was opened and active work began on January 1, 1914. The American Medical Association, the American Surgical Association, the Western Surgical Association, the Southern Surgical and Gynecological Association, the American Public Health Association, and many other sectional, state, and local medical societies have since indorsed the

Public health suffers because so few of the people have been sufficiently informed of the advantages of health supervision.

"All persisting lumps or other unusual conditions in women are suspicious -- It might be cancer. --- Please see a good doctor."

The public health nurse affords a means of enjoining precaution when and where it may be expected to become effective.

movement and appointed cooperating committees. The American Association for Cancer Research is made up of that group of scientific investigators working to ascertain the cause of cancer and the most effective methods of treatment, and many of its leading members are also active in the educational work of the newer Society. The various medical journals of the country are constantly rendering the finest cooperation in this respect.

The purpose of the Society, as stated in its constitution, is "to disseminate knowledge concerning the symptoms, diagnosis, treatment, and prevention of cancer; to investigate the conditions under which cancer is found; and to compile statistics with regard thereto." The Society, operating throughout the United States and Canada, is constantly enlisting the cooperation of all forces and agencies, lay as well as professional, which can assist in its twofold purpose of public education and statistical research.

Like all other national public health organizations, the American Society for the Control of Cancer is favored with a generous amount of purely volunteer service. This fact alone has made it possible for the Society to carry on its many activities with success and to keep the importance of the subject constantly before the medical profession and the general public. The campaign for the control of cancer is not surrounded with the popular appeal enjoyed by that for baby welfare or child health; nor does it lend itself as readily to public support as does the attack against tuberculosis or even the venereal diseases which were given so much attention by the Government during the war.

It was, therefore, thought best by the founders of this movement not to attempt to maintain a large staff of salaried officers but rather to call upon the members of the profession whose interest was already crystallized by a long and sorrowful experience with this disease, to prepare information and carry it to the people by literature, lectures and wise publicity. While this has entailed an immense amount of work upon the members of the Board of Directors and Executive Committee as well as those special committees appointed for

the purpose of making a definite investigation or writing a pamphlet on some particular phase of the cancer problem, it has insured to those contributing to the support of this work that the major part of the funds collected went straight into the preparation and distribution of educational material.

Methods of Control Employed

The American Society for the Control of Cancer, which during the past few years has taken a recognized place among the half dozen leading public health agencies of the country, now stands as a liaison agency between scientific investigators of the cancer problem and the various social forces and agencies through which the practical knowledge of cancer control may be carried to the general public. The Society maintains a headquarters office in New York City with an executive secretary and

two assistants and stenographers, and acts as a bureau of information for the circulation of literature, statistical data, suggestions and methods to be used by state and local committees and workers. No less than eighty thousand pieces of literature have been sent out during the past year to physicians, boards of health, nurses and social workers, women's clubs, medical and

"This formula was brewed by Hawk-Eye, Chief of the Choc-taws in 1611. Never fails to cure epitheliomas and neoplasia."

"Everybody at the factory got one today. - Had we known these things four years ago, father would still be with us."

Cancer is a disease of adult life which destroys its victims at the peak of their productiveness, and when they are most essential to their families. Measures are needed to detect early signs.

A credulous, uneducated public is forever the dupe of quacks and charlatans. The specious promises held out by advertisers of sure cure remedies do not deceive a well informed people.

news writers and to state and local workers for distribution to the public.

State and city health departments are supplied with authoritative articles on cancer for publication in their bulletins and with suggestions for leaflets, posters, exhibits and statements to local newspapers.

Suggestions regarding educational methods and reports of work elsewhere accomplished are sent to medical societies and particularly to their committees on cancer and on public health education. Speakers are provided for professional meeting in the effort to assist in bringing the latest knowledge of malignant disease to the attention of the general practitioner through the regular channels.

Efforts are made to instruct nurses and social service workers with regard to the elementary facts about early cancer, so that they may be pre-

pared to advise people, especially women, with whom they may come in contact.

Lectures are given under the auspices of women's clubs, church and civic societies, and other organized groups and to employees of large industrial and commercial organizations. Speakers are suggested for public meetings in any state, city, or town.

Through a carefully supervised press service, the Society secures the publication from time to time of popular but reliable newspaper and magazine articles on this disease and the methods for its control.

In carrying out its design of organizing statistical investigations the Society has conferred with representatives of the leading American research institutes, hospitals, insurance companies and public health departments. The Committee on Statistics endeavors to secure the standardization of state and city reports and has initiated studies of the experience of life insurance companies and records of cases treated in general and special cancer hospitals and clinics.

The Society has urged improvements in the methods of collecting and publishing statistics of death from cancer throughout the United States registration area. At its suggestion the Director of the Census ordered the publication of a special report on the cancer mortality of 1914, which was published in 1916. This is probably the most detailed and comprehensive statistical report on this disease ever made by any government.

Early in the year 1920 an admirable set of sketches in color, drawn by R. Phillipps Ward, an eminent New York illustrator, was prepared and taken to New Orleans for the annual meeting of the American Medical Association. This exhibit comprised fourteen panels and was designed to show, by simple pictures in serial form, the essentials of the cancer problem from the standpoint of the layman. One series of seven showed the right and usually successful way of treating cancer by going at once to a competent physician and fearlessly following his advice in getting rid of the malignant growth; while the other series showed the wrong and usually fatal method in which the patient, ignorant of his danger, by seeking treatment from an advertising "quack," loses his chance for a cure. The contrast between the competent doctor and fearless patient in the "success" and the careless doctor and indifferent patient in the "failure" is well

brought out by the artist, and the sequel showing the happy, intact family in one case and the widow striving to provide for her children in the other, brings forcibly to mind that cancer is a disease of adult life and destroys those at the peak of their productiveness and when most essential to their growing families.

There is an increasing demand for lantern slides for illustrating cancer lectures. The cancer exhibit has been photographed and made into colored slides and a special committee of the Society is now engaged in the preparation of several new sets, with accompanying outlines, for use by lecturers. These will include sets on the male and female genito-urinary system, cancer of the breast and a series showing the lymphatic drainage system of the body and those organs and structures most likely to be involved with metastases from cancer in various locations.

Arrangements are being made by representatives of the Society appointed by the President, to keep the subject of cancer control constantly before the profession as well as the public. Every state medical society in the country has been asked to provide at least one meeting each year on this subject for its members and also one public meeting, and the other national medical and surgical bodies as well as the various sections of the American Medical Association are being encouraged to make a feature of this subject in their annual programs.

Much is hoped for in the future by the extension of "cancer weeks" such as those held in New York

City, Denver and throughout the state of Ohio last year. Also from advisory, diagnostic and demonstration clinics such as those conducted in Scranton and Sayre, Pa., during what were known as "cancer days." Each of these efforts was a success, and whether such campaigns are limited to educational features designed to instruct the public by means of lectures and literature or whether they include the holding of clinics for the mutual benefit of the practising physician and his patient by providing expert consultation on the individual cases, such activities cannot but prove valuable in the general movement for the ultimate control of this disease.

Another venture to which the Society is looking forward is the preparation of a moving picture on the cancer problem. It is realized that the cinema is the most valuable single method in the whole educational armamentarium of quickly

"The nurse was quite right. Early treatment makes that hopeful. --- The lump must be removed."

It is the incipency of disease that needs to be sought for and recognized by the unfortunate victim if the annual toll of unnecessary deaths is to be reduced.

reaching a large number of people, with any message, and the Society now plans to avail itself of this modern means of mass education. A scenario has been prepared and it is anticipated that funds will soon be available for one or more films on this subject.

Heretofore the Society has functioned principally through other organized agencies, general and local, lay and professional, which might assist in carrying its message of cancer control to the public. During the past year, however, following the election to the presidency of Dr. Charles A. Powers of Denver, a widely known and extremely energetic surgeon, the Society has decided upon a more extensive organization scheme whereby every state in the Union will have its own committee and various local committees directed by prominent and interested members of the profession.

Under this thoroughgoing plan, conceived and carried out by the volunteer efforts of a group of the most representative physicians and surgeons of the country, the Society is assured of a most active and successful campaign in the immediate future and will shortly be prepared to inaugurate a movement for uniform effort in which the whole country may advance in unison in an educational attack on this disease.

WHAT IS YOUR REACTION TIME?

METAPHYSICIANS and philosophers have long sought a satisfactory explanation of the psyche, without arriving at any close agreement in their theses. Physiologists, impatient with an explanation of mental phenomena on the basis of an integrating and ordering principle superimposed from the outside, have made it their task to prove that man is simply a reacting mech-

consciousness, and the approval or disapproval evinced by the "ego," which censorship is really a mental process of comparing the new experience with former experiences or habits found to be useful or socially acceptable. Behavior, then, becomes the crucial test of efficiency, and training must have as its object the extension of knowledge and the completest possible organization of such knowledge. A man's mind is the self-conscious counterpart of all his world.

The type of personality depends upon such organizations, and upon their availability, and tests of mental fitness must largely resolve themselves into the number and variety of possible reactions, and the time limit of response. New tests, therefore, have been evolved for a new generation. The picture shows an examination in Germany which is conducted twice a year to enable poor but intelligent children to attend higher grammar schools. They do not undergo the sort of examination which is usual in America, but are given a technical psycho-analytical test. Special machines enable the examiner to determine not only whether or not the subject has a steady hand, but also whether he or she is quick witted or energetic. The curves on an electrically operated dial give the subject's "index" clearly. Efforts are being made to extend this method of examination to trades in the interest of better placement, so that the boys and girls will be directed into occupations suited to them and in which they may reasonably be expected to succeed. The universal and intelligent application of some such method of estimating aptitudes would prevent the wasted effort in trying to put square pegs into round holes. S. P. M.

PROGRAM OF HEALTH SERVICE

The building program of the United States Public Health Service calls for the construction of hospitals with a total capacity of 21,615 beds by the end of the next calendar year, according to *The Modern Hospital*. With the 9,045 beds now provided in hospitals owned or under lease to the Government, this will give the Public Health Service a total of 30,660 beds to care for discharged, disabled soldiers, sailors, marines, and war nurses.

The estimated cost for the construction and equipment of these hospitals is \$87,608,575. This estimate allows for a 10 per cent increase for the cost of building material, equipment and labor, over estimated cost.

The urgency of immediate construction is manifest in consideration of the fact that the Service, although operating only 9,045 beds in its own hospitals, is caring for more than 14,000 beneficiaries of the War Risk Insurance Bureau by contract arrangement with private hospitals and has a large number of applications from discharged soldiers for hospital care which it cannot meet because of the overcrowded conditions in private institutions. On this account, an urgent building program, involving the construction of hospitals with a total capacity of 8,830 beds, is being carried out, which will enable the Service to care for those men in its own institutions.

The two-year program calls for additional construction of 905 general beds, 5,530 tuberculosis beds, and 6,350 neuro-psychiatric beds. Thus, the total number of general beds to be constructed will be 2,605, at an estimated cost of \$8,466,250, exclusive of the cost of equipment, or of the 10 per cent increase covering the possible advance in the cost of building; the total number of tuberculosis beds will be 12,400, approximate cost, \$17,972,500, and the total of neuro-psychiatric beds, 11,060, estimated cost, \$22,225,000, exclusive of equipment or increase in construction cost.

ESSENTIALS IN MEDICAL EDUCATION

WITHOUT attempting to give a complete report of the Annual Congress on Medical Education, Licensure, Hospitals, and Public Health, certain outstanding lines of thought are worth noting and emphasizing. The discussion on medical education seemed to indicate considerable dissatisfaction with present methods and to show that efforts are being made to remedy present defects. A discussion of the so-called "pre-clinical" subjects indicated a rather unanimous feeling that it is necessary to effect a saving of time without cutting down on the hours required on fundamental preparatory subjects. Physiologists believe that more time should be devoted to physiology and that physiological studies could and should be undertaken by the student under the direction of the department of physiological research.

One difficulty which was emphasized by several speakers was the lack of men suitable to be trained in the so-called "pre-clinical" branches. Dr. Edmonds, pharmacologist, made a plea for closer team work between the pharmacologist and the clinician in the wards. Ewing also emphasized the necessity of getting more men studying and being trained, and he pointed out that greater inducements would be necessary to obtain sufficient men. Emerson laid particular stress on the necessity of a closer relationship between the laboratory work and the observations in the ward. It is not sufficient to let the student get a report—he should see the results of the laboratory tests; or better still, do them himself. After all, laboratory diagnosis is not a branch of medicine distinct from the ward work, but is a part of the effort to study the disease in the individual patient. Emerson also spoke on the present method of beginning pre-clinical work in the dispensary. He believes that the first training in clinical work should be in the wards of the hospital where

the individual case can be followed through, whereas, in the dispensary the situation is more like that of private practice. The study of the history of medicine would help a student in differentiating the results of scientific investigation and the prejudices and traditions which enter into medical teaching.

Sedgwick believes that more time should be given to pre-natal work, to the normal child, and to dietetics. In a discussion of the Emerson report, Ewing emphasized the importance of differentiating in the student's mind primary and secondary symptoms of disease. This seems to be a point of great importance, especially in some schools where the teaching of medicine seems to consist in an effort to incorporate as much knowledge of as many things as a student can possibly crowd into his brain.

The question of the general practitioner in contrast to the specialist as an object of medical training was discussed. It is highly important that the fundamentals of medicine be taught by men who are scientifically trained, for only in this way will the specialties be sufficiently indicated and interest stimulated for extending studies into the several special fields, and in the meantime for correlating the subjects so that at the proper junctures conferences will be sought with the specialists. Wilson made special emphasis of the necessity of developing characteristics in a student rather than imparting knowledge. The most important characteristics are thoroughness and honesty. It is better to go to the bottom of one subject than to cover many with less precision.

Cabot's long paper will not be discussed in detail. Mention should be made of his statement that it is important to encourage individuality in medical schools since there seems to be a tendency in certain sources to mould all medical teaching in the same form.

EDITOR.

CONCERNING MINOR AILMENTS

BY I. A. GALDSTON, M.D., ASSISTANT DIRECTOR OF HEALTH COMMUNITY COUNCILS OF NEW YORK CITY

THE subject of minor ailments merits major consideration, this to amend somewhat for the long neglect to which it has been subject, and to emphasize its inherent importance and practical value. Nearly everyone is acquainted with the classic story of the boy and the dike. Few, however, realize how fittingly the moral of the story applies to the health of the individual. That a pinky-size break in the guarding Netherland walls might have led, if unattended, to the ultimate breakdown of the dike and to the destructive flooding of the plains which it guarded, is commonly well understood. That a similar overwhelming of the plains of good health by the waters of disease may take place through a break in the defensive powers of the body is not so well understood. Yet the principle in both instances is the same. So long as the walls of defense are intact there is a maximum of safety. Once there is a break, safety is lowered and, with no recreative activity counteracting and limiting the destructive process, the disintegration of the impaired organism advances along the lines of geometric progression. In simpler terms, as long as the health of a man is normal his defensive powers against all infectious diseases are sufficient to keep him normally healthy. Once, however, because of the neglect of some minor organic or functional ailment his health is less than normal, his defensive powers are lowered, broken, and an avenue of invasion is made clear for some destructive microorganism. The seriousness of the consequence, following such break, depends upon the type and extent of the microörganic invasion, its virulence, and upon the stand made by the "second line of defense," i.e., the local and general organic reaction to the invading foe.

Build Lines of Physical Defense

This thought of minor ailments and the individual's defensive powers demands emphasis, because, to the mind of the layman, minor ailments are minor matters, and certainly to some extent he is correct. But beyond their immediate importance there is the importance of what minor ailments may lead to, and this the layman sees not at all, or but dimly. Bad teeth in themselves—of what little import—he will say. But bad teeth with root abscesses and ever replenished pockets of pus draining into the blood with every heart beat seem less harmless. The first appear to threaten no more than some aches, some disfiguration, and possibly a fetid breath; the second, however, may lead to multiple neuritis, or inflammations of the nerves, to septic endocarditis, or heart diseases, to impaired eyesight, to pus kidney, and to any one of another hundred nameable and none too happy conditions.

Examine the average layman and he will readily see the first; the second and more important consequence—the complications—he cannot know specifically, and does not see generally. Yet, the complications liable to spring from so termed minor ailments, depending as they do upon an infinite number of contributing factors, and operating as they must under circumstances ever varying, are in themselves infinite in number. Any attempt to enumerate them would give near to the entire category of the known diseases in all their possible combinations. Further, no pathologic conclusion or picture incidental to such an enumeration might reasonably be deemed impossible since to medicine the most serious consequences have been

known to follow the least of injuries. Thus, anthrax or malignant pustule has followed a razor cut, and general septicemia has been known to result from a pin prick. Given any malcondition, provided it is associated with some break in the normal body defense, speculation as to consequence may have free rein with no fear of outstripping reality to check it. Such consequences, however, while possible, are fortunately not common and, though many a man lives for months on a 40 per cent basis of efficiency and strength, few of the pin pricks suffered result in more than the initial sting, and a most negligible percentage of razor cuts lead to anthrax infections. Most of the consequences are not so immediate nor so startling, though it should be added all are sufficiently serious.

In reviewing the subject of minor ailments one cannot but remark how readily the theme lends itself to a "calamity presentation." It is so easy to fall into the style of the nostrum advertisement wherein is paraded before the poor duped victim an array of the most distressing conditions that might result from the very ill which this bottled or boxed panacea promises to cure. It is tempting to present the unusual, the uncommon, the startling, the interesting. The more significant, the less sensational, somehow proves not so attractive. Yet in the study of the sequences of minor ailments, the truly important factors are not to be found nor to be perceived in the septicemia case following the pin prick, nor in the anthrax case, but, on the contrary, are to be found in the tables of life expectancy, in the indexes of death rates, and in the various other statistical data bearing upon the vitality of our people. For the minor ailments are not so dangerous in the immediate distress or fatality they may induce as because of the slow, certain, and insidious manner in which they sap the vital powers of the individual, robbing him of the reserve meant for old age and emergencies, and laying him bare to murderous assault by the many evil forces that operate about him.

Vital Power Shown by Death Rates

As a matter, both independently interesting, and bearing directly upon the last point of contention, may be presented the fact that while through various health activities the hazards of life have been reduced to an extent resulting in the prolongation of the life of the average person of the ages from one to thirty-five years, the life expectancy for the average from thirty-nine and upward has been reduced to an equal extent, so that the man of forty today may not expect to live as long as his grandfather did. Incidentally, it may be worth noting that this is true for the United States only and that in Europe the death rate per thousand, which is another way of expressing the same factors, has been declining constantly and for all ages.

These facts, when stated, require examination and interpretation. Undertaking this, the very first question that presents itself is why do the mature men of today die younger than did those of grandfather's time. The answer very evidently is that modern life is more strenuous, and, while undoubtedly there is much truth in the answer as it presents itself, it demands further elaboration. Life today is more strenuous, that is, there is a greater tear and wear upon the living individual of today than there was fifty years ago. But certainly the mode of

life now current somewhat compensates for the increased tear and wear, or else the death rate were increased for all ages and not, as it is, increased but for those past middle life. Certainly, too, the assured constancy and superior quality of our food supply, the improved sanitation in the procurement, transmission, and disposition of milk, water, and garbage; the increase in number and the improvement in operation of our hospitals; the development and extension of our boards of health—all must contribute to the improvement and prolongation of life, all of which should, and to a certain extent does become evident in a lowering of the death rate. Yet, to repeat, despite these various factors tending to improve the conditions of existence and, therefore, to lengthen life, men and women in the late mature years have less of life to expect today than formerly.

Nature Penalizes Neglect

The first answers being thus proved incompetent, it but remains to probe the problem further, and a solution suggests itself through the expression "the tear and wear of modern life." That it is so is granted. The life of today is more intense, in the common vernacular is "of greater speed." But increased speed brings with itself the need for increased and improved care in the operation of the human machine. Possibly it is in the lack of this care, in the neglect of minor ailments, that the cause of the mentioned increased death rate is to be found. There is hardly another solution to the problem in hand that suggests its completeness and validity so forcefully and so convincingly as the last. Certainly, if we understand minor ailments in the broadest sense possible, this suggested solution becomes absolutely convincing.

The significance of this last point might perhaps be made clearer through a quotation taken from the late Dr. Osler's masterful dissertation on tuberculosis. This master clinician's view of the body as a soil wherein the seeds of diseases become implanted and flourish in the degree of its susceptibility and fertility can happily be as well applied to minor ailments as to the specific affection tuberculosis, and it is quoted here for this very reason. The passage reads:

Many years ago I drew the parallel between infection in tuberculosis and the parable of the sower, which, though now hackneyed, illustrates in an effective way the importance of the nature of the ground upon which the seed falls. "Some seeds fell by the wayside and the fowls of the air came and devoured them up." These are the bacilli scattered broadcast outside the body, an immense majority of which die. "Some fell upon stony places." These are the bacilli that find lodgment in many of us, perhaps with the production of a small focus, but nothing comes of it; they wither away "because they have no root." "Some fell among thorns, and the thorns sprang up and choked them." This represents the cases of tuberculosis, latent and active, in which the seed finds the soil suitable and grows, but the conditions are not favorable, as the thorns, representing the protecting forces of the body, get the better in the struggle. "But others fell on good ground and sprang up and bore fruit an hundredfold." These soils wherein infections spring up and bear fruit are the soils made fertile for destruction through the neglect of the common laws of health and through the slow but certain lowering of the organic vitality and natural defensive powers through the operation of neglected minor ailments. Observance of the first and attention to the second would make us all "stony places whereat no seeds of diseases can take root."

To the mind of the average man busy in the pursuit of individual interests, and not commonly given to thinking in social figures, the facts enumerated may present no special significance. It is so far from a deflected septum or an infected tonsil to a life expectancy table that the mind and imagination of the untrained mortal is lost

in the stretch. But relations exist, perceived or unperceived, and these cold tables of death rates and life expectancies are staggering in the seriousness of their revelations. For the interest of our greater community it becomes essential that we develop a social vision competent of a correct perspective and embrace of social matters. It is important too that this social vision dwell on health, and learn to see the very grave and serious relations existing between the untended minor ailments and the vital status of our people. McBride¹ in his presidential address before the American Neurologic Association, held in Atlantic City in 1919, speaking on the social loss from diseases pointed out that:

"The annual social loss from disease is equal to the destruction of a great war. This is all the more to be regretted because most of it is preventable. It is a serious thing that there are more than six hundred thousand deaths from preventable diseases in this country every year. Four hundred times the number that were lost on the Titanic, a tragedy that shocked the world. Three hundred thousand babies die before they are a year old, a loss of which the figures are a poor measure. More people die before they are fifty years old in the United States now than in the time of our grandfathers, though in several European countries more people live beyond the fiftieth year than was the case two generations ago."

These facts and figures tell but the merest bits of a most discouraging tale. To them should be added the economic losses due to inefficient work, the many millions of days lost in preventable sicknesses, the untold of suffering springing from the vicious circles of poverty, illness, and worse poverty and much else. But the tale told and the causes enumerated, what then? Then comes the melioration. Stirred to action by the knowledge of all sequents of the violation of the common laws of healthful living and the neglect of minor ailments, it is for the conscious elements of our communities to direct its activities to the elimination of the causes and the simpler factors behind these.

How Health Habits Are Evolved

First should come education, education in the laws of proper living; education which will begin in the public school and be extended throughout the individual's school life till he is, at least, as well acquainted with the geography of his own being and its physiology as he is acquainted with the geography of the United States or the correct analysis of a sentence. Though it is not possible to suggest these lines of activity in any form of graded importance, perhaps the second emphasis should be placed upon a systematic agitation and education for periodic physical examination. It is the philosophy of the ostrich, ill becoming to man, that "what I see not or know not of isn't going to affect me." Yet many a man refuses to visit his dentist and his doctor for fear that the first may find a cavity to fill or a tooth to extract, while the second might order a life extending vacation which would interfere with business. It has been the experience of physicians examining insurance applicants that many a man first learns of his weakened heart or impaired kidneys, or hardened arteries when rejected by the insurance companies, men who might have been saved such serious consequences by a timely examination which would have led to a modification of their mode of living.

This most culpable neglect of the human machine by man himself stands out more glaring and consternates the mind of the physician and health worker the more when in contrast to this neglect of self we note the care he bestows upon the common machines he employs in his daily life.

1. McBride, James H., M.D.: *The Physician and Human Conservation*, MODERN MEDICINE, October, 1919, p. 528.

What motorist but yearly overhauls his motor car. What housewife but properly cleans and oils and examines her sewing machine. Universally, each spring and fall sees extensive housecleaning. Here the furnace is examined, there the plumbing, in a third place the roof, in another the woodwork, and everywhere damages are repaired and things mended. It is the human machine, most previous of all, that is so universally neglected. How very human!

To create the demand, however, is but half the task; to supply it is the other, and with the agitation and education for periodic physical examination there should be developed the agencies through which such physical examinations may be had, minus the pecuniary embarrassment that would be suffered if practised under present conditions. A complete physical examination requires the services of several experts whose services requires the use of costly equipments, and whose combined fees under the present status of medical practice are far too burdensome for the average income. The high cost of expert service is, however, as much due to the relative infrequency with which it is required as to its very expertness, and with the creation of a greater demand the sum total return for services would be increased, while the relative costs would decrease. If such agencies were organized as part of the greater public health machine, it would readily become possible for the average person to secure all the requisite expert services required in a thorough physical examination without undue financial strain.

Health Through Community Effort

The development of these agencies are not to be looked for as spontaneous social developments independent of directed community efforts, and, since such efforts can come only after an understanding of all factors involved, the matter again resolves itself, like a correct mathematical proposition, to the original answer—education. Education, or the knowledge of matters and methods, will make the average man recognize the importance of minor ailments and the true wisdom of a stitch in time, and will bring into being the community movement for the creation of the required social agencies of health. Education will also prove the effective solution for all associated problems.

As stated in the Memorandum on Malnutrition,² “the socialization of knowledge is the first ingredient of a true panacea—the other ingredient is a conscious and intelligent pursuit of the ends so pointed out. To the three R’s—without the possession of which no man may be deemed even rudimentally educated—should be added the fourth R, standing for the Rules of Health, and the last should be as firmly insisted upon as the first. The community councils here may prove efficient instruments. Not only can they serve immediately as educative agents conducting open forums for the instruction of their mature members, but also they can bring pressure to bear upon the proper sources, with an aim toward modifying the curriculum to include a more extensive study of hygiene than is given at present.

Education, however, covers a multitude of sins and by its vagueness brings despair to the hearts of those who seek a concrete something in the fog of Social Activities. But it really need not do so, for, if it has been vague in the past, it may be given specific meaning at present.

We have already defined education as a knowledge of matters and methods, and our educative activities should serve to acquaint people with these. The matters should dwell on the people’s proper sphere and the sphere’s problems—the methods—should be directed toward the improvement of the first and the solution of the second. The

instruments for the teaching of both are to be found in our existing educational institutions, and can be made to serve through proper application. The public forum ranks high in effectiveness as an educational instrument; the lecture platform, the public schools, and the public press can prove equally efficient under different circumstances. The existing public health organizations can also be made more effective in their labors by being brought closer to the people, this implying no more than a greatly broadened acquaintance on the part of the people with the activities and aims of the health institutions.

This memorandum which begins with minor ailments now ends with education. As is maintained throughout these pages, the two are intimately associated, the first as the problem, the second as the solution; the first as a *particular* problem, the second as a *universal* solution. And the councils, in the opinion of the author, achieve only where they educate, where they teach thought and action. Each community, of course, has its individual problems which require individual treatment. It is hoped, however, that this general statement may serve as a guide to the proper understanding and efficient solution of these particular problems.

SAFETY IN CONSERVATION OF VISION

It is a fortunate fact that when factory lighting is made very good, it ceases to be merely an expense and advances into the class with income producing investments, according to John A. Hoebler, of the Industrial Commission of Wisconsin, in *Safety*. Because of the importance of good lighting in reducing accidents, conserving eyesight, and increasing production, the illumination of a plant is worthy of as much attention as machines and tools. When natural light fails, there must be provided a substitute equal to daylight in enabling the eye to see, if the shop is to produce on the scale of daylight efficiency. The following tests are suggested by Mr. Hoebler to determine the efficiency of artificial light: (1) Is the illumination received at each working position sufficient for the particular operation? Any shop man can be the judge of this, even though he cannot design the lighting installation; (2) Is it possible to look from one end of the shop to the other without straining the eyes, or do numerous exposed or partly exposed lamps interfere with comfortable vision? If such a view may be taken without straining the eyes, the chances are good that the man at the machine will not be hindered by glare, by which is meant “any brightness within the field of vision of such a character as to cause discomfort, annoyance, interference with vision, or eye fatigue.” In cases where the work is on polished surfaces additional protection must be provided so as to eliminate bright reflections in these surfaces; (3) Is it possible to work without causing unavoidable sharp shadows on the work? If these three requirements are satisfied, then the main items that go to make up an adequate artificial lighting system are present and one may be assured of good results.

On women we must depend, first and last, for personal and household health—for preventing the family from degenerating in as far as these things are concerned. Would not the true way of teaching the art of preserving its own health to the human race be to teach the female part of it in schools and hospitals, both by practical teaching and by simple experiments?—Florence Nightingale.

INDUSTRIAL HYGIENE IN GREAT BRITAIN

ALTHOUGH in the teaching and practice of industrial hygiene Great Britain has a good deal to learn from America, yet signs are not lacking that employers of labor and factory proprietors are beginning to become awake to the fact that it pays to have workshops of every description in a good state of hygiene in every particular. If workers are not well or are discontented—a symptom of mental sickness—the work is not done as it should be and the employer suffers the most in the long run. The laws regulating factories and workshops here are, in the main, excellent, and, on the whole, efficiently carried out. They are uniform throughout the entire country and an industrial revolution of a happy kind is in progress.

In dangerous and unhealthy trades perhaps the greatest factor in improving conditions has been the introduction of artificial ventilation, with the enlargement of shops in proportion to the numbers employed. The war has given great impetus to scientific research, and has done much to help in the hygienic improvement of the condition of industrial workers by the discovery of harmless substitutes for poisonous ingredients and the rapidity with which the new affections introduced during the war by the handling of T. N. T. and aeroplane dopes were dealt with is testimony to advance in methods of caring for the workers' health. Of course, at one time the sanitary and hygienic conditions of the factories and workshops of Great Britain were deplorable, not to say scandalous. Child labor, which was then usual, has been abolished altogether, in which respect this country leads America. Long hours of work have been reduced enormously, the most exhausting forms of labor have been minimized or abolished by the introduction of mechanical appliances.

However, there is still a vast difference in the manner in which factories are conducted, and it is to the credit of the big concerns, that, as a rule, they acknowledge their responsibilities to their work people by keeping their houses in order from the sanitary and hygienic standpoint. Where America is in the van, is in the hygienic and esthetic management of factories and workshops. Their laws as to sanitation, generally speaking, are not so good as in Great Britain, because they vary in the

several states. In some of the states the laws in this direction could scarcely be bettered; in other states they are lax in this respect; but the American employer is more solicitous of the welfare of his workers than the British employer. Yet there are now many British employers who look after the health and well being of their employees most conscientiously.

Neville Chamberlain, M.P., president of the Section of Industrial Hygiene at the Sanitary and Hygiene Congress held in Birmingham in the autumn of 1920, in the presidential address described work being done by a Birmingham firm for its employees in the way of industrial hygiene. The medical service of the firm comprises a central and four branch surgeries; a wheeled ambulance is kept at each branch and a motor ambulance at the main surgery. Trained nurses are in constant attendance and a visiting doctor attends each day at a quarter past two for as long as required. There is no charge for treatment; his salary is paid by the firm. A dental surgery is run in connection with the main surgery and advice is given free; treatment may be obtained and paid for by deduction from wages if desired. For recreation, a clubhouse and grounds comprising thirty acres have been provided. The clubhouse contains accommodation for holding committee meetings, debates and lectures. There are a billiard and chess room, library, tea rooms and separate common rooms for girls and men. If a member wishes to give a family party, a room may be reserved for the occasion. A subscription of five shillings (\$1.25) is charged. The playing fields and tennis grounds are provided with pavilions in which light refreshments can be obtained and dances held.

The factory is constructed so as to provide every facility for air and light. The maximum of light is obtained by constructing the windows so that they reach to the ceiling and only a very narrow tier of brick separates them. By the arrangement it is very unusual to have to use artificial light, in the day time, but a special study has been made of the placing of lamps, with a view to securing perfect illumination, continuous artificial ventilation by dust exhaustion and fans insures the removal of swarf, small pieces of metal and other substances likely to cause dust. Landings and staircases are cleaned daily. From 12 o'clock on Saturday night until Monday morning all windows are opened and all floors thoroughly cleansed.

Lavatories with hot and cold water, soap, nail brushes, and towels are provided, the latter supplemented if workers desire, and services of drinking water are laid on. There is a gymnasium with shower baths for boys and girls, for which no charge is made. While progress has been made, industrial hygiene is yet rather a collection of experiments than an organized science, and the path to future progress lies more in prevention than cure. It is the human machine which must be studied and attended to, and the human machine differs in essential respects from the mechanical machine. The source of human energy is mental, and must be kept in the highest state of efficiency. It is not sufficient to protect the worker from disease, to have a perfect sanitary and hygienic equipment, or even to place at the disposal of all the resources of medicine and surgery. His mental powers, their strength and limitations, must be considered, and this statement is even more true of woman than of man on account of what Sir Almroth Wright has termed her physiological disabilities. More accidents occur through mental than physical fatigue, and the question of industrial hygiene must be regarded from the psychological as well as the physiological point of view. Monotonous labor

dulls the mental powers, and rest and amusement are indicated in order that labor may yield of its best. The cheerful worker is a zestful and good worker, but he cannot be cheerful if the monotony of the work bores him. In the recently introduced Ministry of Mines Bill it is proposed to establish a fund provided by a statutory levy of one penny (2 cents) per one ton on the industry for the special behoof and for the recreation of the miners.

LONDON CORRESPONDENT.

CZECHS COMPEL TREATMENT

The Division of Social Pathology in the Ministry of Public Health of Czecho-Slovakia is advocating the passage of a bill in parliament which provides for compulsory treatment of the infective stages of venereal diseases and requires every city of more than twenty thousand inhabitants to provide a dispensary for the free treatment of venereal patients. Advertising of cures and quackery will be prohibited, and physicians will have the right to report all patients who do not apply for treatment regularly during the infective stage of the disease.

THE PHYSICAL EXAMINATION OF EMPLOYEES*

By A. W. COLCORD, M.D., MEDICAL DIRECTOR, CARNEGIE STEEL COMPANY, CLAIRTON, PA.

WHEN I was a young man, many years ago, I was greatly impressed by a lecture I heard at a teacher's institute, entitled "Pedagogus Cui Bono." "The Teacher—For Whose Benefit?" If we could paraphrase this we would have a more appropriate name for this contribution—"The Company Doctor—In the Rôle of Physical Examiner—For Whose Benefit?" When the great steel strike was called one year ago, the unions made twelve demands, and one was—the abolishment of physical examinations. This is an indictment on the face of it, and there must be something radically wrong with our whole system of physical examinations or the workers would not only be satisfied with them but would demand their continuance.

Where Our Opportunity Lies

Why have we failed to convince labor that these examinations are mainly for the benefit of the employee? Have we undertaken this job in just the right spirit? Have we grasped the opportunity? Have we let the "protect the company" idea cloud our vision and shut out the broader, better view? Here is our chance to help the man become healthier, happier, more efficient, to live longer; our chance to make him feel our personal interest in him; to start him on the way to become a loyal contented member of the great big family that runs our plant. Are we letting this chance slip? Someone has said, "we examine the new man to keep out the unfit and fit the fit." This is all right as far as it goes. It is well to select the men who are adapted to our needs and to find just what job each can do best; but this is not enough. We must not only fit the fit, but must make the fit fitter—and we can often make the unfit fit.

There are times when the industrial surgeon can serve his company best by not serving it. Whether on the witness stand, in the emergency hospital, or in the examina-

tion room, the surgeon is not an advocate for the company, but a just judge—an apostle of the "square deal," and if he must lean, let it be toward the employee. If nine days are lost each year from sickness by each worker, and if, as we are told, one-half of this sickness is preventable, we must first find out the causes of preventable sickness, and then set about preventing it. We may do this along four lines: (1) Better working conditions in the mill; (2) better living conditions in the home; (3) finding out and arresting disease in its early beginning; and (4) adjustment of the man's life to suit his physical condition.

So much has been said about care of the eyes and teeth, and about tuberculosis that they are mentioned only to emphasize their importance.

There are especially two fields where more work needs to be done and where our minds remain somewhat unsettled. One is the hernia question¹ and the other is the heart. Our profession is just waking up to the importance of heart disease; to the fact that it is one of the greatest three causes of mortality; that it often disables the victim for years and, most important of all to the industrial physician, that, if caught in time, it may be cured or arrested. We owe much to Sir James Mackenzie for teaching us the relative unimportance of heart murmurs; that it is function, after all, that counts, and that we may detect these signs of heart failure early—while the heart is still efficient—and so regulate the patient's life that he may have many years of usefulness.

Vagaries in Examinations

Before the passage of compensation laws, examination of employees was unusual among the great industries. About six years ago the Carnegie Steel Company instituted the routine examination of men, gradually extending the practice into its various plants. Since that time we have at the Clairton plant examined about twenty-five thousand men.

1. Colcord, A. W.: Hernia: Should It Be Classed as a Compensable Injury or a Disease?, *Pennsylvania Med. Jour.*, August, 1918.

*Read before the Joint Meeting of the American Association of Industrial Physicians and Surgeons with the Health Service of the National Safety Council, September 29, 1920, Milwaukee, Wis.

As more than twenty-seven states now have compensation laws, the employers of labor have felt that their own protection called for some form of examination. These examinations differed according to the needs of the particular industry, but more often varied with the ideas and hobby of the medical director of the company, some employing the most cursory inspection without stripping, others requiring a two hour examination and going over each case with great thoroughness. Some examiners place the greatest emphasis on eyes and ears; some are strong for tonsils; some think the teeth the main thing; while others concentrate their energies on looking for and trying to cure tuberculosis. Then we have the hernia enthusiast, the man who looks especially at the feet for fallen arches both major and minor, hallux valgus, etc.; the heart specialist; the man with tobacco and alcohol phobia; the expert who would measure the man's mentality with a Binet test or his physical endurance with a muscle testing machine; the genito-urinary man who puts his applicant through the third degree as to gonorrhea or syphilis; and the laboratory man who would find out the most necessary things by making blood counts, urinalysis, Wassermann, and blood pressures. These are not mentioned to the disparagement of any one of them, but only to show to what lengths a hobby may carry a man. Out of all this we should select what is necessary and best.

In our physical examinations we must not lose our sense of perspective—must not exaggerate one feature or minimize another.

There is good in each one of these hobbies, but we must not ride it too hard.

I believe, aside from the clerical work, a fair idea of each man can be obtained in an average of ten minutes.

Some such routine as the following is useful:

(1) Height and weight, obtained by a clerk outside.
(2) Applicant comes into examining room *stripped and alone*.

(3) Examiner makes rapid, systematic inspection—noting his gait, carriage, appearance of skin, muscles, joints, any scars, deformities, limp, or stoop. One learns to unconsciously note his apparent age, mentality, nutrition, signs of dissipation or ill health, signs of physical training, as of a soldier or athlete. To the trained examiner all this and much more is apparent in the few seconds elapsing while the man enters and walks up to the examiner. It is well to follow some definite outline in this inspection at first, till it becomes a habit, such as beginning at the top of the head and going downward, to include hair, eyes, face, neck, shoulders, arms, hands, chest, abdomen, genitalia, thighs, knees, legs, ankles, feet, toes.

(4) Greet the applicant cheerfully and in a way adapted to his personality. This cannot be taught, but is one of the most important things in the examination. Many applicants are nervous, some are frightened, and some ugly at having to submit to an examination. Some are inclined to be over-familiar with the examiner. The greeting must be such as to quiet the nervous, allay the fears of the frightened, win over the grouchy one, and command the respect of the over-bold and familiar. Above

all, this first greeting must win his confidence and make him feel that the physician is his *friend*. When this is accomplished, we have won the battle, and he will tell anything we wish to know, will willingly submit to anything we may find it necessary to do in our examination, and he will help and not hinder the process.

(5) Having made the preliminary inspection and placed him at his ease, he may now be placed on the examining table so as to go over him more closely again, beginning at the top of the head and going downward. In my own work I prefer to do this with the applicant standing.

The eyelids are everted and examined for trachoma or other disease. The cornea is inspected for scars or ulcers, the pupils are noted for inequality, irregularity, or immobility.

The teeth, mouth and throat are then inspected. It seems unnecessary to make a record of each tooth, but a general record may be made of the conditions of teeth, tonsils, etc.

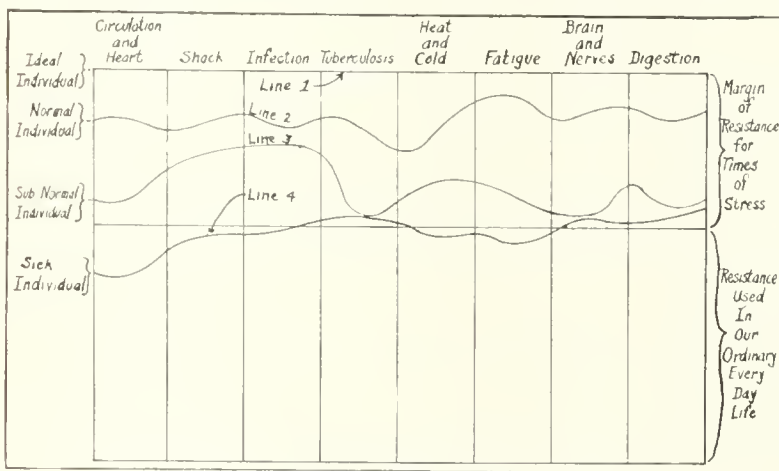

After noting the condition of ears, neck, cervical glands, thyroids, etc., proceed to the shoulders, arms, and hands, noting especially signs of previous injury, stiff joints, or old fractures. Then pass to the chest and with a stetho-

scope, or the ear and a towel, and rapidly listen to heart and lungs.

The first inspection will usually indicate which points to emphasize in each case and whether a thorough chest examination is needed. Note chest development, deformity, or asymmetry, getting a history from patient of empyema scars, area of dullness or flatness, protracted coughs, pneumonia, or pleurisy.

We then pass to the abdomen, palpating spleen, liver and appendix. The hernial regions are gone over, as the patient coughs, first inspecting, then palpating the rings, and lastly invaginating the scrotal skin over the little finger into the external ring. I have classified open hernial rings into three degrees, according to whether patulous or lax. A normal ring admits the little finger with difficulty. An open ring of first degree admits the little finger easily, but has a firm border to the ring and shows little or no bulging on coughing. An open ring of the third degree has widely open ring, admitting middle finger or thumb, with distensible border—open canal—usually with a weak aponeurosis on posterior wall of canal. If the inner ring can be felt and will admit the finger, there is probably a hernia, although it may not be possible to get it out on coughing or lifting. We note the condition of the whole hernial region, observing any weakness of muscles and any signs of operation or truss-wearing. An enlarged gland, an undescended testicle, or a varicose vein over inguinal canal is not to be taken for hernia. The condition of the spermatic veins and evidence of bubo or its scars, varicocele, hydrocele or scar tissue from old orchitis or epididymitis call for closer observation. Acute gonorrhea, chancre, or chancroid will, of course, be in evidence if present.

The thighs, legs and feet then come in for attention,

No two men show the same physical characteristics, but their resistance may be estimated by a balance struck between weaknesses and points of especial strength, not overlooking the personal equation of intelligence, adaptability, and the will to win.

noting stiffness of joints, scars, deformities, varicose veins, edema, ulcers, flat feet, hallux valgus, etc., at the same time noting the presence or absence of skin eruption or scars of operations or wounds.

The examination of an applicant becomes, with long practice, much like the reading of a page of proof by an experienced proofreader—he goes rapidly over a whole page and sees very little unless some such error as a misspelled word, a letter upside down, or an omitted capital, stands out from the page and instantly arrests his attention.

With long practice, the going over in this way of a large number of men can be reduced to an average of about ten minutes for each man. The healthy man with nothing to note will require about six minutes, while here and there a bad case will require fifteen or twenty minutes.

To test the eyes and ears will require two or three minutes to be added to the average time. In railroad employees the color test will require one or two minutes more.

A Summation of Findings

Having completed his examination and written on the card all important points, there remain to be considered:

(1) The grading as entered on the card: I usually have in mind a marking on the scale of one hundred. Loss of a finger counts five; great toe five; twenty one-hundredths vision in one eye five; a stiff elbow in one arm otherwise strong ten; loss of two fingers ten; a deformity of leg or hip causing a marked limp ten; deafness in one ear five to ten; partial deafness in both ears five to ten; stupidity five to ten; stuttering or stammering five to ten; hollow chest, stooping shoulders, poor nutrition, bad teeth, sallow complexion, heart lesions, old lung areas of consolidation, all having a value according to their gravity and especially in their bearing on his usefulness as a worker. Having his percentages in mind, the rest is easy: From 90 to 100, A; from 80 to 90, B; and below 80, C. The "C" man is employed only after conference with the chief employment officer. Complete loss of one eye or one leg or a hernia, grades to eighty or below and makes a man a "C." Whether to employ such a man with our present compensation laws is a debatable point. Many companies do employ them and place them in selected positions. Active venereal disease or other contagious or infectious disease should temporarily reject a man. An exception should be made for scabies or pediculi if the man takes measures at once to rid himself of them. Trachoma should reject while active and showing pus in the eye. We have allowed cases of trachoma to work after the acute stage had passed, provided the man used his own basin, soap, and towel, and kept himself under the treatment of a competent man till pronounced cured.

(2) Estimation of resistance: In the evolution of a race, whether of plants or animals, resistance is most developed along lines of the strongest attack. An oak is an oak because the winds have blown it, the winter has frozen it, the summer suns have scorched it, and the drouth has tried to dry it up—it and its ancestors—for thousands of generations. "We are what we are because we have been doing what we have been doing." At those points in our wall of resistance where we have been subjected to the greatest stress, we have developed a special resistance. Our bodies have built up through the ages a mechanism for withstanding fatigue, shock, various poisons, the different infections such as tuberculosis or erysipelas, hemorrhage, hunger, heat, cold, heart strain, mental strain, dust, thirst, loss of sleep, deprivation from oxygen or sunlight. From the cradle to the grave our life is a constant struggle for existence. Beset with foes without and within, we gather strength by the fight we make. We slowly learn to adapt ourselves to our surroundings, to the life we must live, to the things we must do.

Health is an adjustment of the body to its environment. Each organ has this power of adjustment within certain limits. When this limit is exceeded, injury and disease result. The heart adjusts itself to running, walking, sitting or lying, the blood pressure adjusts itself to the

various conditions, rising in cerebral compression, arteriosclerosis or uremia, and falling during sleep or shock. If continued strain is put on the heart its walls enlarge and thicken. If intra-abdominal pressure increases over a considerable period of time the muscular walls become thicker and stronger. This is especially true in manual laborers and it is this compensatory strengthening of abdominal walls that usually prevents the laborer from getting hernia more frequently than the clerk.

If we were to represent these lines of resistance graphically, the straight line at the top would represent a perfect individual existing only in our imagination, the "Wonderful One Hoss Shay" of Oliver Wendell Holmes. In the normal individual the line comes well up at all points, showing a good margin of resistance everywhere. The subnormal line is that of a man whose resistance is low at one or more points, coming down near the danger line. He cannot stand stress at these points. The lowest line represents a sick man. He has not enough resistance to lead even an everyday life, and he must be turned over to someone competent to treat him until his wall is built up at this point.

It is the business of the examining physician to locate the top line of the man's resistance; to find where he is strong and where he is weak; what he can stand and wherein lies his danger. He must estimate the man mentally and physically—his aptitude to fill a responsible position—his endurance—his ability to keep himself or others from danger, and his resistance to disease or exposure.

(3) Personal conference with the man as to his condition, his care of his person and of his health. He will, if we have used tact up to this time, tell us freely of such of his past history as we need to know, including his habits and way of living—good or bad. We now tell him as much of our findings as we think is good for him to know—show him what bearings these may have on his future health, happiness or longevity—and direct him what to do, or where to go to have his teeth fixed, his eyes corrected, his hernia operated, his scabies cured, or any one of the many correctible things we may have found. This personal interview is the psychological moment of the whole examination—the time when we can do much good or harm; we may miss a splendid opportunity to follow up our advantage we have already gained in winning his confidence and respect—by not telling him the things he ought to know. There is no time when we can impress the excessive smoker of cigarettes of his danger as when we have just examined his heart. The man who is intemperate in eating, drinking, or working can be warned of his danger.

If in this examination we have failed to break down opposition, clear the prejudice out of his mind that may have existed against physical examinations, show him that we take a personal interest in him, that we are his friend and are anxious to do him good—if we fail in this, then the examination can be considered hardly worth while and we have wasted out time and energy and the company's money.

Health Supervision Follows

Those cases examined who have remediable deformity, curable disease, or ways of living that may injure their health should be seen at regular intervals, to make sure that they are profiting by our advice. How much pressure should be brought to bear on them to compel their following this advice will depend on the policy of the employing company, and to a certain extent on each individual case and its needs. Certainly there should be some follow-up system, systematically carried out, and every effort should be made to bring every employee up to the highest point of health and efficiency. I have said to a man with a serious error of refraction still uncorrected: "You will be employed with the understanding that you will report to me in ten days with properly fitting glasses." If such a man is not financially able to do this, he should receive the necessary aid.

The rooms for examination may be a part of the plant hospital or may be connected with the employment offices. We have the latter arrangement at the Clairton plant.

The waiting room is used in common with the Employment Bureau. From there the man passes into a dressing room with individual booths. When stripped, he walks into the examination room, which is a room 10x26 feet, with three windows on one side. It is also well lighted by electric lights. The furniture consists of stationary wash basin, desk, swivel chair, two still chairs, and a small high desk for surgeon to write on while making examinations. A rug is on the floor, covered with a square of heavy duck, to be changed frequently. A surgical table is placed at one end of the room, on which the applicant lies during the greater part of the examination.

At the other end of the room are test charts for eyes.

The surgeon should be provided with the usual instruments for examination: scales, for measuring and weighing; stethoscope; blood pressure instrument; urinalysis set; microscope and accessories; tape measure; ruler; ophthalmoscope; nose and ear specula; tongue blades; and head mirror. In cases where some special examination is needed, such as x-ray, blood count, or Wassermann, there should be some arrangement by which this can be done in a nearby hospital or laboratory.

The floor of the dressing room should be covered with some material which can be cleaned daily. There should be a shower bath and toilet connected with dressing room or within easy access.

The above described arrangement is suitable for one examiner only. If there are specialists to examine each man, or even an occasional man, suitable offices should be provided.

All rooms used in examinations should be specially well ventilated, not only for the health of those in attendance but because the air soon becomes very offensive, if not frequently changed.

One or more policemen should be in attendance to guide the men as they enter and leave the examination room.

Some doctors prefer to have a clerk present to record the findings. I am aware that this is a great saving of time and relieves the doctor of much work, but it destroys the privacy of the examination and robs it of the close personal relation between doctor and applicant. For this reason, I prefer to do my own clerical work during the examination. One hears much discussion about where, how and by whom examination cards shall be filed. Certainly there should be some system used making them easy of access. In my opinion they may be filed by an employment clerk and attached to the employment card—filing by check number, with a cross index by name. When needed by the doctor, he has only to ask the employment clerk for the man's card. We then have the man's whole employment and examination history before us, and in case of re-employment, the same examination card and employment card can be used, with such additional entries as are needed.

The Foreign Laborer

I am aware that the difficulties in examining foreigners who can speak no English are almost insurmountable; yet in actual practice—after we learn how—the difficulties are more apparent than real. After handling large numbers of the various nationalities, one learns to a certain extent how they think and what manner of approach is best suited to them and will best win their confidence.

I seldom use an interpreter and would much prefer to have the man *alone* though I could not speak a word of his language. Of course an interpreter must be used by the employment office.

In the physical examination of female employees I have had no experience, and would very much like to hear this

phase of the subject discussed by someone who has done this work.

I only know that it is being done in some plants with great benefit to all concerned. It would seem almost necessary where women and girls are employed in considerable numbers that they be under the care and guidance of a skillful, tactful, sympathetic woman physician. Those interested in this phase of the work will be repaid by a visit to the plant of the B. F. Goodrich Company at Akron, O.

The applicants for employment, on examination, fall naturally into three groups:

(1) Normals: These will need examinations at regular intervals to make sure they are still normals.

(2) Subnormals: These need—(A) Adjustment of the man to his environment—habits—treatment. (B) Adjustment of the environment to the man. Selection of department, cooperation of superintendent or foreman as to kind and quantity of work he should do. (C) Correction or regulation of his home life. (D) A keeping in touch by frequent re-examination and conferences to see whether he is placed right. How he stands his work—whether he is taking our advice.

(3) The sick: Those who do not have the strength and endurance for even the lightest work or the routine of everyday life. If their case is hopeless, we must return them to their friends and tell them kindly of the fact. If their sickness is curable, we should refer them to the proper place—family doctor, their friends or, if they have no family, friends or means, we should send them to a hospital and assure them that as soon as well and able to work we have a place for them. Those who have contagious diseases, whether active venereal or otherwise, must be sent away until they are not a source of danger to fellow workmen.

Causes for Rejection

This leaves few real rejections: (1) Those whom state compensation laws would penalize us for hiring. Such laws are inhuman and all such portions of the law should be repealed; (2) those hopelessly sick; and (3) those who by mental or physical unfitness would be a source of danger to fellow workmen.

In installing a system of physical examinations in a plant, I would suggest that we should provide for the following:

- (1) Complete examination of all now employed.
- (2) Examination of all applicants.
- (3) Re-examination of all who leave the service of the company, one month or longer, and return.
- (4) Re-examination of all employees at stated intervals.
- (5) Special examination of an employee who has just passed through a severe sickness or has had a serious injury. Also a man who shows in his work that his health is failing or that he is losing his efficiency.

Special Examinations

In times of epidemic of contagious disease it may be necessary to make daily examination of all contacts. We have done this during several smallpox epidemics, allowing contacts to work in a crew by themselves, out of doors, and having a doctor or nurse inspect each man daily, including temperature.

During the great influenza epidemic of 1918 we had 1,000 men in our bunk houses. The influenza hospital was equipped early with two graduate nurses in charge and each bunk house was inspected daily by an officer. Every suspicious case was at once examined by doctors or nurse and, if flu was suspected, he was taken to the flu hospital and isolated. When the cases were convalescent, they were kept several days in a convalescent hospital before being allowed to return to the bunk house. Although from 30 to 60 per cent of the inhabitants of surrounding towns had flu during this epidemic, only seventy cases, or 7 per cent, developed in our bunk houses.

In addition to the routine examinations there should

be a careful examination made of each case of slight sickness occurring among the workers. Attention may be called to these cases either by (1) visits to the hospital by men while working, for slight ailments such as headache, toothache, indigestion—we average seven such cases daily in our emergency hospital; (2) cases found during visits of our welfare nurse; (3) cases referred by foremen, superintendents, or fellow workmen; (4) disease detected while attending to any injury.

The way these cases of ambulatory sickness were handled in some of our military camps during the "late unpleasantness" is an illustration of how it should not be done. In one large camp in the Middle West these men lined up and were rapidly questioned and as rapidly classified into two great groups, the respiratory group and the stomach and bowel group. The former got Brown's mixture and the latter castor oil.

If we are going to run a dispensary for our employees who get sick at the plant, let us run it right. Let us give each one such examination as his case warrants. Let us give him careful medication and advice and then either refer him to his family physician or follow up the case ourselves until we are sure he is well.

During the trachoma epidemic a few years ago, I examined two thousand eyes in two days and one night, working continuously with the aid of one nurse. Twelve positive cases were found and twenty suspects. An eye specialist went over these cases, confirmed the twelve and added three cases of suspects to the positive list.

Of the positives, all were treated and all cured but one. The suspects were given weekly and then monthly examinations for several months. The positives are still under observation. There has been one recurrence. I use the word "cured" here in only a relative sense and regard trachoma "curable" in about the same sense as we can speak of curing syphilis or gonorrhea.

Why Institute Examinations

Good and sufficient reasons appear in all of this for the routine physical examination of the men. The outstanding benefits of such a régime may be briefly stated as follows:

(1) To sift out the physically, mentally, or morally unfit. In addition to rejecting the man with hernia, or the man with only one eye, one hand or one foot, it is just and wise to reject the degenerate, the man with active venereal disease, the chronic alcoholic, or the drug addict.

How far we should turn our mill into a home for the ruptured and crippled, a school for the feeble-minded, a place of reform for the vicious, or a Keely Cure, rests with the management; but if we are going to do any of these things, we should do them with our eyes open.

(2) To make a systematic and permanent record of the imperfections of those whom we do employ—the fingers missing; the crippled hands; the crooked elbows; the stiffened knees and hips; the flat feet; the corneal scars; the open hernial rings; the deaf ears; the flat chests; the heart murmurs; the scars of wounds and operations; the badly set fractures; the missing or decayed teeth; the rapid pulse; the exophthalmic goitre; the enlarged glands; the stuttering and the stammering; the hare-lips, cleft palates, varicoceles, hydroceles, pigeon breast, and hallux valgus; the alcoholic breath and dilated facial capillaries—and so on through the long list.

We should find out and record these things: (a) that we may more intelligently treat our employees when sick or injured; (b) that we may be better protected against the malingeringer; and (c) that we may more accurately estimate the damage we have done to the man if we injure him.

(3) To help us help the man; that we may put him in the right way to get his errors of refraction corrected; his hernia operated; his scabies cured; his teeth repaired; or his heart saved from further damage.

(4) It forms one of the best points of contact between

employer and employed. If the examining surgeon is the right man in the right place; if he is kind and courteous; sympathetic and tactful, cleanly in his habits and attractive in his personality; if he has the gift of getting the confidence of the stripped stranger in one minute and keeping it; if he has the rare common sense to know just how much to say to each man—he can soon overcome all opposition to examination of employees. He can make the examinations one of the most popular and useful things about the mill. He can do much to make the new employee into a loyal worker. He can start the men toward better health and more efficiency.

(5) The men already working in the mill have a right to be protected against contagious or infectious disease; against the vicious, the hopelessly stupid, and the degenerate; against the man too blind or too deaf to protect himself or others from danger.

(6) Examination has shown us the frequency of certain diseases and conditions among the workers, and has placed us in a position to grapple the problem as a whole.

(7) The conscientious, thorough, systematic examiner receives a valuable training in this work, becomes more and more proficient in rapid, accurate diagnosis, and acquires a wide knowledge of men and a rare judgment in the placing of them that must be of great value to his employers and a source of satisfaction to himself.

(8) As the years go on, and as we do more and more of this follow-up work; as the improvement in health and efficiency of the workers becomes more apparent; as the great importance of preventive medicine is borne in upon us; as we look beyond the mill to the homes of the workers and see the appalling amount of preventable sickness among the men and their families, we shall feel the need of systematic, regular examination of all the *well*; we shall catch disease in its incipency; we shall study the causes of sickness and remove them.—Then and not till then will the industrial physician have fulfilled his mission and come into his own.

(9) Finally, examination of employees, done in the right spirit and with the proper "follow-up," is in keeping with the trend of the times toward better living, better and healthier homes and mills; more help to the fellow that really needs it; and toward that feeling of brotherhood which must come if we are to solve the problems that confront us.

DOCTORS CAN PRESCRIBE BEER

The opinion handed down by Attorney General Palmer, March 3, before he retired from office, holds that it is not within the power of the Internal Revenue Bureau, through regulations, to limit the number of permits which may be issued for the manufacture and sale of spirituous, vinous or malt liquors for medicinal purposes, except that permits for retail sale are limited to reputable druggists who are pharmacists or who employ a pharmacist.

This ruling takes from the Bureau the power to refuse permits for manufacture or sale, where application is made, even though the Commissioner believes a certain number of permits would be all that was necessary to take care of legitimate demand.

THE TYRANNY OF DIRT

A hundred years ago people shuddered at the name "Gaol fever," a terrible pestilence, which attacked judge and jury, prisoner and onlooker at Old Bailey. We call it typhus fever now, and it is rare in Britain, thanks to the enthusiasm of the early nineteenth century hygienists. It is a dirt disease, it can be controlled by care and cleanliness. It is due to a microbe, not yet isolated, which is transferred from man to man by infected lice. As Sir Ray Lancaster says, the Angel of Death they spoke of a hundred years ago is the clothes louse, which can be readily exterminated by the use of benzine. We cannot but feel that it was almost contemptible to have submitted for centuries to a tyranny of dirt; but the point is that we are continuing to submit to similar things. We are slow to learn the lesson of Control of Life.—Thomson.

FOCAL INFECTIONS AS AFFECTING TRIVIAL INJURIES

BY C. D. SELBY, M.D., TOLEDO, O.

THE inflammations that were formerly known as rheumatism are now generally recognized as chronic infections of secondary origin. The foci from which these metastatic infections are derived appear most frequently about the teeth and jaws and in the tonsils, sometimes in the sinuses, and occasionally in the intestinal and genito-urinary tracts. They seldom cause noticeable symptoms; nevertheless, they are the source of bacteria and toxins which pass into the blood stream with more or less regularity. An immunologic reaction results from this constant contamination, but the balance between health and disease is occasionally so delicate that any slight lowering of resistance may disturb it and allow the infection to become active in the area affected.

Sequelae to Simple Injuries

The process is serious because it is insidious. Being quiescent, the primary foci attract little or no attention. Causing no sudden active disturbance, the blood stream infection arouses no suspicion. Beginning perhaps with a trivial injury, such as a contusion or a sprain, the local manifestation causes no alarm. The whole process is one of gradual development, and perhaps the first intimation the patient has of trouble is that he is not recovering from an injury quite so quickly as he should. Even so, he may continue optimistic and even apologetic. "It was a little worse than I thought," he is prone to explain. Then, sooner or later, he realizes that he needs medical advice and seeks it, only too frequently to learn that the trouble has progressed so as to baffle medical skill.

Although many of these local manifestations of focal infection make their appearance without apparent reason, a great many of them do seem to follow injuries of a more or less trivial nature; in fact, patients are often inclined to blame injuries for their localizations, and with some justice, for we now know that the hyperemia and stasis which follow injuries, however, inconsequential, are enough to cast the local balance of power to the infection.

If the patient is so employed that he may become a beneficiary under a compensation act, and the injury he alleges has been received under circumstances that would entitle him to compensation, he is then quite within his rights if he makes claim for compensation for disability arising out of the sequel to the injury, or the local manifestation of a focal infection, even though the focus is the principal cause of his trouble. In such a case, and under the law, the injury would be regarded as having accelerated or aggravated a pre-existing condition.

Trivial injury plus focal infection equals compensable disability. In the light of the foregoing, the duty of physicians is clear cut. They should:

- (1) Determine what kinds of trivial injuries are most apt to be followed by infection of focal origin; and,
- (2) When injuries of this type present themselves, seek for foci of infection and endeavor to secure their eradication.

This program is an application of preventive medicine as well as curative medicine. It seeks to prevent disabilities, sometimes of the most discouraging and discomfiting varieties, and aims to save the state social and economic losses.

Physicians have another quite important duty with regard to these cases. This is:

- (3) To pass upon the validity of claims for compensation arising out of disabilities due to metastatic infections, alleged to have been the effect of injuries of a more or less trivial and, in themselves, non-incapacitating nature.

As Affecting Compensation

This question is often extremely perplexing. Nevertheless, if the evidence of injury is authentic, the pathology of the effected part is definite, and the existence of a focus of infection is proved, then the presumption is justified in favor of the validity of the claim.

The most common varieties of trivial injury in which metastatic infections may be expected are as follows: (1) Simple fracture of a terminal phalanx; (2) Contusion of the end of a digit; (3) Sprain, particularly of the knee, wrist, ankle, elbow, shoulder, and hip joints; (4) Strain, especially of the back, deltoid and gluteus muscles.

Phalangeal Fracture

Fractures of the terminal phalanx are very baffling, largely for the reason that they appear to be so trivial. They are apt to be taken for contusions and treated as such. If the fracture severs the artery to the distal fragment, infection is almost certain to ensue, and recovery cannot be expected until the fragment is excised.

All contusions of the ends of digits should be considered as fractures until proved by the Roentgen ray to be otherwise. The Roentgen ray will of course establish the fact of the fracture, but it cannot prognosticate the infection. The continuity of the blood supply is the principal factor in that, and there is no method for determining it except that of waiting for developments.

The ideal method of treating these cases is to eradicate the infectious foci and remove the denourished fragment. It is the usual experience, however, that patients think the treatment out of proportion to the injury and refuse to submit to it. The course most often pursued is: (1) Splinting of the digit; (2) observation over a period of several weeks; and, finally; (3) removal of the fragment if infection has occurred.

Contusion of End of Digit

In the fleshy part of the end of each digit there is a fascial sac. If a contusion causes bleeding within this sac without rupturing the sac itself, and, if there are foci of infection elsewhere in the body, an infection will probably occur in the sac. The first thing to be done in cases of this character is to incise the sac. This lets out the blood, relieves the tension and therefore the pain, and greatly lessens the chances of infection, even though no primary foci are removed. Should primary foci exist, the patient should certainly be fully informed of the danger, and given the privilege of determining the course he wishes to pursue.

It is very rare that a patient considers either a fracture of a terminal phalanx or a contusion of the end of a finger sufficient cause to warrant the removal of his tonsils or the extraction of some teeth. Almost without exception, the patient will say, "Well, let's wait and see how it turns out."

Perhaps a physician is not warranted in insisting upon the removal of primary foci as a means of preventing the possible development of trouble in connection with an in-

jury to a finger, but there is positively no question as to the justification of such a measure as a means of preventing the development of an arthritis, or a myositis, or a neuritis, because all three are capable of producing life long incapacity if permitted to become well established.

Of course the ideal procedure in these cases, as in all, is to make a complete physical examination; but it is seldom that a physician feels warranted in going so thoroughly into a study of a case that is apparently of a trivial nature, nor does the patient expect him to do so. Nevertheless, for his own protection, a physician certainly ought to investigate the possibilities of focal infections by examining those parts of the body that are most frequently affected by them.

The following routine is therefore suggested in connection with the treatment of all joint injuries, whether severe or trivial, and all muscle contusions if they are not too trivial in their nature:

(1) Inspect the mouth for bad teeth and infected tonsils.

(2) Examine the sinuses for evidence of infection. If the patient gives the history of having a chronic nasal

discharge, this is pretty suggestive evidence of a sinus infection.

(3) Go into the history of previous conditions of health and, if the facts are suggestive of chronic intestinal intoxication, or a genito-urinary infection, appropriate examinations and laboratory tests should be made to determine the existence of infectious foci in either of these two tracts.

(4) If foci are discovered, the patient should be fully informed as to what he might expect, and he should be advised to have the foci removed.

(5) During this time of investigation the injury should be given the usual method of treatment. This does not differ in any way from the treatment ordinarily accorded contusions and sprains.

(1) Foci of infection should be looked for in all cases of (a) injury to the ends of digits, in all (b) joint sprains, and all (c) muscle strains.

(2) Such foci should be removed whenever possible; because foci of infection may cause these injuries, whether trivial or severe, to become chronic inflammations of a markedly incapacitating nature.

FIELD HOSPITALS IN CONSTRUCTION WORK *

By J. P. CLEARY, M.D., DU PONT ENGINEERING COMPANY, DETROIT, MICHIGAN

THE importance of field hospitals in construction work is steadily gaining greater recognition. They have, indeed, become an indispensable part of organizations in that particular field of labor. It is my purpose, or rather my desire, to suggest some data from which a firmer conviction may be gained of their value; value that is both practical and altruistic. It may be added that full discussion of the subject in all its ramifications would consume more time than my readers have to give, and hence only the main ideas relating to the matter will be advanced.

In the initial stages of these components of the complete scheme of a working plant, rendering first aid to the injured seemed the end at which to aim, but field hospital service has obviously become extended far beyond that original scope. It now incorporates within the bounds of its efforts the conserving of the general health of the workmen, their social welfare, and their relative fitness for the tasks they assume.

The efficiency of the worker in the strict line of his employment is easily seen to depend to a certain degree upon his home life, his general environment, and the entire social status. These facts appear, perhaps, to savor of some sort of scientific theory, and invoke sociology or kindred ideas of wide projection, but one gains easily the notion that herein science is not entirely technical, nor the principles too involved for application in industrial and labor problems.

A Matter of Mutual Benefit

Accepting as axiomatic that the interests of both the employer and employee are identical in the last analysis, it behooves all concerned to consider in some detail the practical advantages of field hospital service.

The employer derives what may be styled a mercenary benefit, but he also enjoys the reflex action of practical humanity. The time, the very essence of constructive work, which would otherwise be wasted by removal of an

injured workman to a hospital or physician's office some distance away from the immediate field of labor, is saved, and also the attendant expense. The employer has the chance to show sincere sympathy for the suffering employee by providing the means of caring for the injured on the "home grounds." Then, quick conveyance to some distant hospital or office entails in itself aggravation of the accident or disease. Measured in dollars and cents, elements to be watched in these days, the economy of treatment nearby cannot escape attention. The opportunity to administer instant remedies, or make quick diagnoses, and thus obtain a grasp upon the malady or injury immediately, can easily be figured by business men in terms of money. The return of the employee to his work as quickly as possible is an important consideration, and in this desideratum employer and employee share equally.

The cost of installing and maintaining a hospital is more than offset by the advantages derived. Insurance companies give a lower rate on liability insurance to concerns maintaining a first aid station at their plants. The expenditure for the physician's services, the supplies used, the equipment, and all other expenses can be easily ascertained, but it would be difficult, indeed, to determine the actual monetary returns from the investment, for the influences of the plant hospital are wide and numerous.

In the construction of a plant for the Cadillac Motor Car Company in Detroit, Mich., the Du Pont Engineering Company, from August, 1919, to August, 1920, employed, all told, about 17,000 men, the maximum at any one time being about 3,600, and the minimum about 800. Construction work has many hazards, probably many more than exist in industries engaged in operation. During the year referred to there were 4,490 injuries. Eighty of the number were major injuries, necessitating loss of time. Of these eighty injuries, four resulted fatally, one in permanent, total disability, and the remaining seventy-five caused a loss of approximately 14,752 working hours, an average of 196.6 hours per major accident. In addi-

*Delivered before the Construction Section at the Ninth Annual Safety Council, at Milwaukee, Wisconsin, September 29, 1920.

tion to the 4,490 first dressings or treatments administered, approximately 3,229 redressings were required, amounting to 7,719 treatments for injuries, administered during the year.

It is estimated that 3,500 medical cases were treated during this time, making a total of 11,219 treatments given. During the influenza epidemic last winter, on an average of thirty medical cases were treated every day. Of the 11,219 treatments, perhaps 1,432 were required in cases of major injuries, leaving 9,787 treatments administered for minor injuries or illness.

The Matter of Costs

The cost of equipping and maintaining the plant hospital here for the period mentioned amounted to \$6,800. Of this amount, \$5,900 was applied to the treatment of minor injuries and medical cases. Dividing this amount by 9,787, the number of treatments, gives an average cost of sixty cents each.

During this period of time, 15,765 men were examined by the medical department, and 15,615 were accepted, and placed on the company's roll. In addition to this number, there were approximately 2,500 men on the rolls of the sub-contractors during this time, making a total of 18,115 men who were protected by the medical department during the year in question. This amounts to an expenditure of approximately thirty-seven cents for each man so protected.

During the same year there were 366 penetrating wounds of the feet, resulting from stepping on nails. Of that number, two, or 0.54 of 1 per cent, resulted in lost time.

It may be of general interest to know that in the dye works of the Du Pont Company at Wilmington, Del., during the year 1919, with an average working force of 625 men, the compensation paid during that period was only \$6.00, a really remarkable record. In the same plant 7,778 medical and accident cases were treated during the year referred to, at a total cost of \$2,383.41, or an average of thirty-one cents per case. In the first six months of 1920, the Wilmington plant had 1,207 surgical cases, and of that number only five were serious enough to necessitate any loss of time.

To be of greatest value, the field hospital should be centrally located, so that it may be easily and quickly reached by the injured. Its location should be pointed out to all new employees before they start to work. Whenever possible, the employment department should be in close proximity to the hospital, so as to facilitate the examination of applicants for work. The hospital should not be placed in a noisy portion of the plant where the rumbling of heavy trucks or machinery would interfere with the efficient use of a stethoscope in making physical examinations. For industries employing more than a thousand men, there should be a plant dispensary and a physician constantly in attendance. The size and extent of hospital equipment necessary depends upon the number of employees. For an industry employing a large number of men, the hospital should contain a waiting room equipped with chairs or benches, and a quiet office where files and a few cots may be kept, so that employees may lie down to overcome some temporary condition, and return to work within an hour or two. There should be an examining room for the doctor. This room should be quiet, and should contain an examining table, a writing desk, several chairs, and other necessary equipment. It should be closed off from the other rooms, so that confidential conversations with the various employees may be held here. In addition, the hospital should contain a

surgical room, where accident cases can receive immediate attention. An x-ray machine and sterilizing room would also be valuable additions.

Where the number of employees would not justify the expense of maintaining a physician in the plant, arrangements should be made with a nearby physician to take care of accident cases, and to allow his office to be used for the purpose of making the medical examinations. In places where such an arrangement cannot be made, one or two promising men, such as foremen, could be easily trained to administer first aid. In plants engaged in night work, men with such training would be of considerable value. All plants, no matter how small the number of employees, should have first aid kits available for immediate use.

Secured by Mutual Effort

To obtain the best possible results, the cooperation of the employees is necessary. No effort should be spared to bring them to a realization of the importance of reporting for medical treatment immediately after an accident. They should be made to understand that they will not be docked for the time spent in having their injuries treated. To overcome the hesitancy of the workmen about going to the hospital for treatment of slight injuries, a first aid printed slip should be given by the foremen to the injured employees to take to the hospital; this seems to impress upon the injured employee the necessity of receiving medical attention. All injuries, no matter how slight, should be given medical attention, the foremen should be made to realize the importance of this.

Another phase of the value of field hospitals in construction work is afforded by the physical examination of applicants for employment. Contagious and infectious diseases, heart lesions, impaired vision, deformities, malformation, and defects of all kinds, both congenital and acquired, may thus be detected, and unfit applicants can be kept from communicating actual disease to their fellow workmen, or increasing the hazards of accident through their neglect, oversight, or bodily defect. It is needless to remark how this branch of the subject expands upon meditation. It has become a recognized obligation, morally and legally binding employers to eliminate from their forces all whose ailments or defects are such as to enhance the risk of accidents or transmit disease. All must remember how steadily these doctrines of denying employment to the unfit have progressed in acceptance. Human life cannot be placed in jeopardy by careless hiring of the members of the working group.

Use in Minor Ailments

The field hospital service can be utilized to restore to health those temporarily incapacitated by minor ailments. By this means the labor unit is conserved. The saving of mankind has become of supreme importance, certainly of equal and as far reaching value to the future as the conservation of material resources, in the development of which the human factor is demanded. Such care responds to the dictates of modern thought. It spells wider prosperity.

A Question of Attitude

The doctor can be of inestimable value to a construction organization, by a proper and sympathetic attitude toward the workmen, and by his willingness to show the men that the company has their interests at heart, both in physical examination and the treating of their injuries. In the physical examination of applicants for employment, the employee has the advantage of an early discovery

of disease, and therefore a more rapid and sure cure, while to the employer there is a reduction in loss of time due to sickness and epidemics. To those employees with organic diseases, the danger of overwork and hazardous occupations can be shown, and the employer gains by a reduction in risks for compensation due to accident disability, deformities, and death. In advising and treating the sick there is brought to the employees, protection from contagious diseases and to the employer a steadier working force. By efficient medical treatment the employer gains an increase in the general efficiency of the working force, and the good will of the employees.

The field hospital has both the mercenary and the altruistic phase, the ledger showing a profit, and the heart

feeling a warmer pulsation. In conclusion, it may not seem too burdensome to recur to one branch of service not directly within the hospital's scope, but so allied with it that it can hardly be overlooked. It relates to the possibility of the workmen revealing to the doctor their home influences, the grievances, fancied or real, within their homes. It requires no argument to gain agreement that such tribulations affect the efficiency of a workman; perplexity, brooding, suffering, mental anguish, all perhaps the products of transitory unhappiness, impair the usefulness of the employee. Field hospital work affords opportunity for the conscientious doctor to give counsel, and often adjust these differences and disturbing factors in the workman's life.

THE TREATMENT OF ACID AND ALKALI BURNS*

BY A. K. SMITH, M.D., MANAGER, MEDICAL SECTION, E. I. DU PONT DE NEMOURS & Co., WILMINGTON, DELAWARE

THE wounds caused in tissues by acids and alkalis are not strictly burns according to the accepted definition of a burn. Rather such chemicals belong to a class of materials known as escharotics or caustics, substances which, when applied to living tissue, cause its death and produce an eschar or slough. The strong caustics are sulphuric acid, nitric acid, potash, chlorid of antimony, chlorid of zinc, acid nitrate of mercury, bromin, chromic acid, lime and hot iron.

Applied to the skin, they immediately unite with it, killing the tissues to a depth proportionate to the strength and quantity of the caustic. Their burn is self-limited and immediately the caustic has exerted its strength by union with the tissues it is no longer destructive.

The burns may be conveniently classified just as burns from heat are classified: A first degree burn in which only the epidermis is destroyed or inflamed; a second degree burn extending into the true skin and causing its destruction or inflammation; and a third degree burn which not alone destroys the skin but also extends into the underlying tissues. The treatment naturally varies with the degree of burn.

The most important branch of treatment of these caustic burns is prophylaxis or preventive measures, and under this head come all the safety methods observed and the appliances used to render immediate aid in case of accidental spills.

You will notice hot iron classed as a caustic, and many of these innocent looking liquid acids or solutions of caustic alkalis are quite as potent for harm as the hot iron.

First Aid Immediate

First aid, to be of any great value, must be immediate aid. Probably the most valuable is the shower bath and, of course, it must be used before any attempt is made to remove clothing, and every effort made to get a large volume of water between the caustic soaked clothing and the skin. Directly after drowning the caustic, saturated watery solution of bicarbonate of sodium may be mopped on the burned area in the case of acid burns, and a 2 per cent solution of acetic acid similarly used in the case of alkali burns. After this has been liberally carried out the patient should be placed in a physician's care.

In simple first degree burns mopping the burned area with dry gauze and the application of a bland, clean oint-

ment, such as boric acid ointment or burn ointment—which is made of bicarbonate of soda and petrolatum—or oxid of zinc ointment, may be used by spreading a liberal layer on gauze and holding it in place with a gauze bandage. Such a dressing relieves the pain and is sufficient with renewal of dressing occasionally.

In second degree burns the wound should be cleansed of all loose rolled up epidermis, mopped with a mild antiseptic, such as boric acid solution, and an ointment applied on gauze, held in place by a rather loose gauze bandage.

In this degree of burn, blisters are encountered. Small blisters, unruptured, are let alone and larger blisters, where tension is likely to cause pain, are opened by first sterilizing the area with a 3½ per cent alcoholic solution of iodine and a liberal incision is made with a sterile knife near the edge of the blister, allowing its top to collapse and remain. The ointment used in dressing these cases should be absolutely clean, sterile, and mildly antiseptic, and should have a melting point that will insure its non-separation on standing in the surgery and still be of such consistency that it will spread with ease.

The dressings are renewed as the judgment of the physician dictates, more often at first, when discharges are profuse; and, later, at as long intervals as possible, in order to allow healing to progress without disturbance.

The epidermis must grow over wherever it has been destroyed, and this growth takes place from the sound edges of the wound only. The newly formed epidermal cells are exceedingly delicate and easily torn loose by the removal of a dressing, and it is for this reason that dressings should be changed only when absolutely necessary.

Third degree burns are cleansed of all loose detritus and dressed with a sterile ointment as in second degree burns. After three or four days the ointment dressing is replaced by a wet gauze dressing, using a sterile, normal, salt solution. The dressing must be kept wet by repeated applications of the salt solution.

A slough forms in these cases, necessitating a long wait until the sound tissue loosens and throws out the dead material, and all this must take place before healing takes place to any extent.

The use of wet dressings leaves the wound in a very favorable condition for skin grafting, should it become necessary.

The long time required for healing in these cases is due to the slow separation of the slough, and after that has taken place, granulation tissue must fill up the

*Read before the Chemical Section, Ninth Annual Safety Congress, Milwaukee, Wis., September 29, 1920.

sloughed out spaces and a new epidermis grow to cover the entire area.

Healing may be hastened by a careful removal of portions of the slough when redressings are being made; also by keeping down excessive or exuberant granulation tissue growth; and, most important of all, by skin grafting.

The making of numerous small pin point grafts, some of which will grow, will reduce the time of ultimate closure of the wound. In some cases larger grafts, by the Thiersch method, may be preferable.

Shock may be an accompaniment of second and third degree burns. It should be combated by a hypodermic of morphin, and the earlier it is given the better.

The patient is wrapped in hot blankets and surrounded with hot bottles or hot bricks. Care should be taken to cover the warming bricks or bottles with flannel or other material, to prevent burning the patient. Salt solution may be introduced into the system by one of the various methods, to increase the volume of blood. Ordinary stimulants given by the stomach are of little value in this condition.

Burns of the eyes by caustics are given first aid by douching the eye with a watery solution of bicarbonate of soda in the case of acid burns and a 1 per cent or 2 per cent solution of acetic acid in alkali burns, after which a piece of boric acid ointment about the size of a pea is put under the eyelid and carefully worked into all corners by gentle manipulation on the outside of the eyelid. Further treatment of the eyes can best be done by an eye specialist.

In giving this, our treatment for caustic burns, I am aware of the various other treatments used in burn cases, many of which are not without good points; but I believe that the treatment as outlined will give the patient quicker relief from pain and quite as rapid a recovery and with as little scarring as any other method.

MENTAL HYGIENE OF INDUSTRY

Mental power is the greatest force in the world and is still to be studied from the standpoint of industrial production, according to Mary C. Jarrett in a recent issue of *Mental Hygiene*. Of the necessity for a general understanding of the way the human mind works and of social investigation of problems affecting the worker's industrial capacity, she quotes Miss Frances Keller: "Nothing but science has even been able to understand power of any kind. Engineering is the only method that holds out any promise of ultimate success. Increasingly the engineer untrained in man power, but having the essential groundwork, is becoming the manager of men."

This contribution by Miss Jarrett is a report of work done in collaboration with the late Dr. E. E. Southard. It outlines the manner in which the movement for mental hygiene in industry has taken shape and in the interest of developing more exact methods she surveys the present situation and analyzes the inquiry into this subject made by Dr. Southard for the Engineering Foundation. A bibliography of 1,600 titles dealing with the human element in industry was collected and serial studies made which were to have been incorporated in a handbook on the subject, an undertaking that was interrupted by the untimely death of Dr. Southard.

The inquiry developed no lack of evidence in the industrial plants visited that the psychopathic employee is a recognized problem. Usually the cases cited as difficult were among the best workmen, and the problem in each case was how to keep the men at work. The number of workers with actual mental disease is small,

but the harm that may come to any organization because of these cases is out of proportion to the size of the group. The time required to deal with this group intelligently if they are properly understood through medical advice is relatively very little. The second group for the mental hygienist or the individuals who are ordinarily called "difficult," "peculiar," "cranky," "touchy," "irritable," "moody," "disagreeable."

These two groups would constitute nearly half of the average working force, but the efforts of the human engineer would by no means be confined to the workers with demonstrable disorders. The problem of the largest group of workers would be chiefly to develop their mental ability.

Knowledge concerning mental hygiene has been gained largely through the study of mental diseases, and it may be considered as proved that contributions which make for the better handling of men which would be of great practical value to industry have been made by psychiatry and psychology. The time has come for the constructive application in the case of normal workers of the principles of mental hygiene looking toward the improvement of industrial organization. Some points of interest in this subject evinced by personnel workers, industrial physicians, and manager are summarized by Miss Jarrett under fifteen heads, and it would appear that no opposition to progressive work in the mental hygiene of industry is to be encountered from industry. A deterrent might be expected in the fear of the employee that the recognition of mental disorder may discredit the worker, but it will not be difficult to show the employee that the object of mental hygiene is to make him more fit and better able to hold his job.

A mental hygiene program calls for some definite organization. A practical plan is suggested in Dr. Southard's idea of a "mental hygiene working party." Mass methods are not called for; the work must be in terms of the individual. Cooperation on the part of industrialists, especially in respect to the findings recorded in their turnover sheets, would obtain welfare values for the community as a whole.

Increasingly the solution of special problems of industry are found to bear an essential relation to general health problems. Certainly personality adjustments in industry cannot be divorced from family and community relations and with additional instruction and training in matters pertaining to industrial organization the psychiatric social worker should prove an asset to industry.

S. P. M.

STATE CHAPTERS

Pennsylvania, Ohio, and New Jersey have organized state chapters of the National Association of Industrial Physicians and Surgeons. All of the so-called "Industrial States" should have these chapters.

Your Secretary is prepared to render all possible assistance in their organization and will, upon request, furnish a "model" constitution and by-laws.

If you haven't such a chapter in your state, why not get busy and organize one?

WISCONSIN HOME-COMING

The State Medical Society of Wisconsin will celebrate its seventy-fifth birthday by holding a "Home-Coming" meeting in Milwaukee, September 7, 8, and 9, 1921.

The officers of the society are anxious to secure at this time for mailing purposes the names of all former Wisconsin men. They will confer a favor by sending their names and addresses to Dr. Rock Sleyster, secretary, Wauwatosa, Wis.

INDUSTRIAL HYGIENE AT CALIFORNIA UNIVERSITY

THE United States Public Health Service publishes an outline of the course in industrial hygiene given at the University of California. These courses are in four parts: (1) The hygiene of temporary industrial centers, such as mining, lumber, railroad, and military camps; (2) factory and occupational hygiene; (3) industrial accidents and safety measures; (4) health supervision, welfare work and workmen's compensation.

The outline of the course follows:

Temporary Industrial Centers

(1) *Introductory remarks.*—The history and rise of industrial hygiene; its scope. The future of industrial medicine and surgery.

(2) *Sanitation of camps.*—Temporary industrial and military camps. Location of sites; topography, from standpoint of water, drainage, and waste disposal. Camp layouts.

(3) *Water.*—Source of supply. Wells. Purification of water. Permanent and temporary projects. Dangers. Tests.

(4) *Waste disposal.*—Dangers of soil pollution by fecal matter. Latrines and sanitary privies. Septic tanks. Garbage and manure disposal. Necessity for camp cleanliness. Incinerators of different types (illustrated).

(5) *Housing.*—Tents. Bunk houses. Mess houses. Baths. Barns and corrals; relative importance of proper location. Sanitation.

(6) *Food.*—Well-balanced diet. Dangers from human and fly contamination. Food preserving. Diseases due to improper food and disease transmission through food handlers. Supervision of food.

(7) *Insects as disease carriers.*—Life history of the fly; prevention of breeding; means of destruction—fly-traps and other measures. Bedbugs, lice, and fleas. Diseases transmitted by these insects and their economic relations to industry. Disinfection of beds and buildings. Delousing.

(8) *Mosquitoes.*—As disease carriers of malaria and yellow fever. Life history of these insects. Difference between the varieties. Historical review of the discovery of these insects as carriers. Mosquito control. Treatment of human carriers.

(9) *Other camp enemies.*—Hookworm, venomous reptiles, poison oak and ivy, venereal and human-carrier perils.

(10) *Camp diseases.*—Typhoid and other gastro-intestinal diseases. Respiratory and other communicable infections. Value of vaccination. Newer conception of isolation. Isolation quarters.

(11) *Mining.*—Mine gases; explosions; prevention. Rescue and resuscitation methods.

Factory and Occupational Hygiene

(12) *Factory.*—Factory history. Types of shops. The modern factory. Sites. Description. Interiors. Standards for toilet, drinking, and washing facilities. Disposal of factory waste.

(13) *The worker.*—Women in industry. Child labor. Necessity for personal hygiene. Clothing. Care of the teeth and skin.

(14) *Industrial physiology.*—The human machine. Fatigue. Muscular tonus. Rhythm in industry. Overwork. Output. Rest. Day and night work. Men versus women in industry. Economic relations.

(15) *Industrial lighting.*—Artificial and natural light-

ing. Consequences of defective lighting. Need for supervision. Standards. Excessive light. Eyestrain. Preventive measures.

(16) *Ventilation.*—Physiology. Recent research. Air changes produced by human beings. Harmful effects of stagnant air, high temperature, and humidity. Standards. Mechanical ventilation. Dust removal. Excessive heat. Sunstroke and heat exhaustion. Use of instruments. Psychrometer, anemometer, and thermostats.

(17) *Special occupational disorders.*—Disorders of the eyes and ears. Dermatic disorders. Results of fatigue. The neuroses, occupational cramps, etc.. Effects of heat and cold. Postural defects. Effect of special mechanical appliances such as the air hammer and other tools. Processes involving exposure to occupational infectious diseases, such as anthrax. Health hazards will be classified as to industrial origin and the conditions related to the symptoms to be looked for.

(18) *Toxic gases, fumes, and vapors.*—Ammonia, aniline, benzol and benzine, chlorine, methyl alcohol, carbon monoxid and dioxid, sulphur dioxid, "dope" poisons, phosphorus, T. N. T., soot. Symptoms and prevention.

(19) *Toxic metals.*—Lead, mercury, arsenic, chrome, brass, etc. Symptoms and prevention.

(20) *Dusty trades.*—Classification of dusts. Effects of dusts upon the skin and lungs. The tuberculosis problem. Morbidity and mortality statistics. Determination of amounts of dust. Prevention. Use of mechanical appliances, wet and electric processes. Discussion of exhaust devices; respirators. Importance of medical examination of employees.

(21) *Occupational diseases due to harmful environment.*—Caisson disease. Divers and submarine operators. Aviators and high altitude. Symptoms and prevention. Decompression chambers for tunnel workers. Explosives. Gas warfare. Electrical shock. Rescue methods. Artificial respiration.

Industrial Accidents and Safety Measures

(22) *Accident prevention.*—The personal factor in accident causation. Relation to age, sex, ignorance, physical unfitness, carelessness, overcrowding, poor illumination, unsuitable clothing, defective machinery and structures. Falling. Unclean conditions. Monotony of work. Speeding and long hours.

(23) *How to organize for safety.*—Safety committees. The duty of the employer and employee.

(24) *Safety measures.*—Special problems of certain industries. Safeguards in general. Safety devices for the worker. Statistics.

(25) *Factory fires.*—Origin and spread of fires. Control and prevention of fires. Loss of life due to fires. Fire escapes. Fire drills. Rescue. Burns.

Welfare Work and Workmen's Compensation

(26) *Medical supervision.*—Purpose and advantages. Dispensary and hospital facilities. Medical and dental service. Public health nurse. First-aid stations and instruction. Physical examination of employees. Accident records.

(27) *Welfare work.*—The sociology of industry. Factory inspection. Rest and locker rooms. Baths. Restaurants. Recreational activities. Community and home conditions. Reclaiming the tuberculous and the cripples of industry.

(28) *Workmen's compensation.*—Legislation for prevention of occupational diseases. Notifiable diseases. Health insurance. Reports.

CALL FOR ANNUAL MEETING

The annual meeting of the American Association of Industrial Physicians and Surgeons will be held in Boston, Mass., on Monday, June 6, and Tuesday, June 7, 1921, Let us all plan to be there and make this meeting the best one that the Association has ever held. President Geier has appointed the program committee and they are now hard at work in arranging all the details for the meeting; let us express our appreciation of their efforts by being present at the meeting.

Hotel Accommodations

We present herewith a list of Boston hotels and their prices and all members are urged to write immediately and make reservations.

Name	Address	Rates per Day	Number of Rooms
Adams House	Washington and Mason Sts.	Application..	
Arlington	Arlington Square	\$2.00 and up.	
Burkminster	645 Beacon St.	\$3.00 and up.	450 1st class
Charlesgate	Beacon St. and Back Bay Park	\$4.00 and up.	
Essex	Atlantic Ave. and Essex St.	\$1.50 and up.	400— (300 bath)
Ritz Carlton	Boylston and The Hotel	Fens	\$2.00 and up.
Garrison Hall	Garrison and St. Randolph Sts.	\$2.00 and up.	300
Harvard	Huntington and Longwood Aves.	\$2.00 and up.	150
Puritan	390 Commonwealth Ave.	\$3.00 and up.	
Savoy	455 Columbus Ave.	\$1.50 and up.	200
Somerset	Commonwealth and Newbury Sts.	\$2.50 to \$6.00.	
Veredome	Commonwealth Av. and Dartmouth..		

Amendments to Constitution and By-laws.—Article IX of our constitution and by-laws reads:

This constitution and by-laws may be amended by a two-thirds vote of the members present and voting at any annual meeting of the Association; provided, that the call for such meeting shall have specified the particular amendment which is to be acted upon, and provided also that no amendment shall be acted upon which has not been so specified.

In accordance with this provision amendments to Article III, Section 4; Article VI, Section 1, and Article VIII will be submitted at this meeting for action by our members.

HOSPITAL LIBRARY AND SERVICE BUREAU

As a member of the Hospital Library and Service Bureau, 22 East Ontario Street, Chicago, Ill., the following letter is addressed by Dr. Frank Billings, its president, to the American Association of Industrial Physicians and Surgeons:

We have all along realized the need of some source from which definite information, data, and reliable figures on all of the many phases of hospital construction, organization, and operation could be obtained. Interest in hospital work from any standpoint develops at once a call for data and figures on the average of a definite class or a distinct organization. To supply these will require a carefully organized and comprehensive collection of all obtainable data about hospitals for study and advance compilations—that answers may be available promptly.

With financial aid from the Rockefeller Foundation, the American Conference on Hospital Service has undertaken to organize and operate the Hospital Library and Service Bureau to meet this situation. We need cooperation, interest, and assistance from your organization, as an organization, and also from your members individually. It will be necessary to ask many of them for information and it is quite desirable that they be informed as to the purpose of the request and the use to be made of the information and also as to the attitude of your organiza-

tion to this project. They should know direct from you also that their connection with the work of hospitals through membership in the American Association of Industrial Physicians and Surgeons entitles them to apply for and receive, free of any charge, any information and data which the library has collected. We must call attention, however, to the fact that data must be collected before it can be given out and this will require a little time.

Please give this project consideration and such publicity as in your judgment is required properly to inform all your membership in this matter.

MEETING OF PENNSYLVANIA CHAPTER

The Pennsylvania Chapter of the American Association of Industrial Physicians and Surgeons will hold its annual meeting at the William Penn Hotel, Pittsburgh, on Friday, April 15. The whole membership of the National Association is invited for the consideration of the following program:

MORNING SESSION, 9:30 A. M.

Chairman.
Francis D. Patterson, M.D., chief, Division of Industrial Hygiene and Engineering, Pennsylvania Department of Labor and Industry, Harrisburg, Pa.
Address of Welcome
By Hon. Clifford B. Connelley, commissioner, Pennsylvania Department of Labor and Industry, Harrisburg, Pa.
What Constitutes Industrial Blindness?
By Edward J. Stieren, M.D., Jones and Laughlin Steel Co., P. & L. E. R. Co., Pittsburgh, Pa.
By Clarence F. Barnatz, M.D., Pittsburgh, Pa.
SYMPOSIUM ON BURNS AND THEIR TREATMENT
The Paraffin Method
By William O'Neill Sherman, M.D., Carnegie Steel Co., Pittsburgh, Pa.
The Picric Acid Method
By George H. Halberstadt, M.D., Philadelphia & Reading Coal & Iron Co., Pittsville, Pa.
Other Methods
By Hubley R. Owen, M.D., Bureaus of Police and Fire, Department of Public Safety, Philadelphia, Pa.

AFTERNOON SESSION, 2:00 P. M.

Minimum Standards for First-Aid
By C. D. Selby, M.D., Toledo, Ohio.
What Should Be the Attitude of the Industrial Physician Towards Health Insurance Legislation?
By J. E. Sweet, M.D., University of Pennsylvania, Philadelphia, Pa.
The Need for Adequate Records of Lost Time by Reason of Sickness or Accident in Industry
By Bernard J. Newman, consultant in industrial hygiene, United States Public Health Service, Philadelphia, Pa.

NEW MEMBERS ANNOUNCED

The American Association of Industrial Physicians and Surgeons welcomes the following new members: Charles T. Cutting, Philadelphia, Pa.; Harry W. Mayes, Brooklyn, N. Y.; Ben F. Coe, Indiana, Pa.; Donald B. Cragin, Hartford, Conn.; Walter E. Caswell, Brockton, Mass.; James H. West, Cleveland, O.; A. J. Barlow Herbert, Grand'mere, P. Q., Canada; Charles K. Ervin, Cincinnati, O., and Alexander L. Price, Wetherfield, Conn.

Every physician who is engaged in the practice of industrial medicine and surgery should be a member of this national organization. It is the one organization above all others in which he should hold membership. We estimate that there are at least one thousand physicians who specialize in the practice of industrial medicine and surgery who are *not* members of our organization.

They should be members, there can be no question about that; and the way to secure them is by personal solicitation by our membership.

If you know a physician in your town who is practicing industrial medicine, give him an application blank, copies of which blank will be promptly supplied you upon written request to the Secretary, and urge him to make application.

You will be interested in the progress of our Association as indicated by our membership by years:

1916—1917	321
1917—1918	303
1918—1919	241
1919—1920	477

DR. SAWYER GOES TO WASHINGTON

Underwood & Underwood.

Dr. C. E. Sawyer, Marion, Ohio, has recently gone to Washington to assume his duties as physician to the president. In line with the policy of President Harding that affairs relating to public health education and social welfare are of the greatest moment, Dr. Sawyer has been given full authority to direct a thorough investigation into the needs of this subject and on the basis of accumulated facts to work out concrete plans for efficient and economical operation of these matters.

CANCER CONTROL

Little, if any improvement has been observed in the cancer death rate in the past ten years, says the Metropolitan Life Insurance Company in a recent report, although this decade has witnessed remarkable progress in the control of malaria, tuberculosis, typhoid fever and other conditions where preventive work has been rationally conceived and consistently carried out. In the entire Industrial Department of this company the cancer death rate has not varied much from 69 per 100,000 since 1911.

The one encouraging fact in the cancer mortality data of the industrial department during the decade is the slight downward trend of the rate for white females. There has been a gradually increasing death rate from cancer among colored females and colored males. The rate for white males has been practically stationary. It may be true that the efforts of the cancer control campaign have been successful in bringing more of the accessible and more readily recognized early cancers of white females to the attention of the surgeon, and that many deaths from these conditions have been postponed. This is the first suggestion we have had in our figures that the moderately developed anti-cancer movement has begun to influence death rates.

Health officials and executives of private organizations would do well to inaugurate local educational activities for cancer control. In Cincinnati, recently, an organization known as the Divisional Council on Cancer Control was effected. This group is under the joint auspices of the City Health Department, the Academy of Medicine, and the Public Health Federation. The work is to be managed by a Committee of Fifteen, carefully selected from the several religious, nursing, medical and health educational groups in the city. It is planned to carry on an intensive system of lectures among women's and mothers' clubs and other organized groups who may desire to be informed on the subject. There is also to be an arrangement with the local newspapers for bringing the

facts of cancer control to the attention of the public. Denver recently held a series of popular meetings on cancer control. Bringing the message of cancer relief to the attention of the public through local educational effort can be furthered by health agencies, especially since the American Society for the Control of Cancer now has local representatives in nearly all States who are prepared to cooperate in developing such campaigns.

CHILD HEALTH DEMONSTRATION

The National Child Health Council, consisting of representatives from six national organizations either wholly or in part engaged in health work for children, has announced plans for a child health demonstration in some one community of the United States. Much is to be gained from the demonstration of a comprehensive and well balanced child health program that can be applied to constructive child welfare work on a national scale. Announcements will be made within the next few weeks of the plans of the Council as to the selection of the community and of the conditions which are considered desirable in order that the demonstration may be of the greatest value.

EUGENICS CONGRESS

The Second Annual Eugenics Congress is announced to be held in New York City September 22 to 28, 1921, the inquiry of the Conference being directed toward the results of research in questions of race improvement dealing with (1) research in the domain of pure genetics in animals and plants and studies in human heredity; (2) the consideration of factors which influence the human family and their control, this to include facts of improved and of unimproved families and the persistence, generation after generation, of the best as well as the worst characteristics, (3) the topic of human racial differences covering migration of races, the influence of racial characteristics on human history and the teachings of the past with bearing on the policies of the future, and (4) the discussion of eugenics in relation to the state, to society, and to education.

MEDICS MEET IN CHICAGO

Underwood & Underwood.

The Council on Medical Education and Public Health, which convened in Chicago during the week of March 8, was attended by more than two hundred leading physicians and surgeons from all parts of the United States and Canada. The picture from left to right shows Maj. Gen. M. W. Ireland, surgeon general of the United States Army; Col. J. F. Siler, of the Medical Corps; Dr. W. L. Carter, Galveston, Texas, and Dr. H. D. Arnold, of Boston, Mass.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. WINSLOW, DR. P. H., *Editor*

OBJECTIVE STANDARDS IN TUBERCULOSIS WORK

WITH the growing tendency to attempt an evaluation of the real efficiency of public health work along various lines, it becomes of increasing importance to devise objective quantitative standards by which various specific activities may be judged. In the course of a recent survey conducted in Rhode Island¹ the attempt has been to formulate certain standards of this kind in respect to tuberculosis,—standards which, though crude and unsatisfactory, may serve as a stimulus to others for the development of the adequate criteria which are so sorely needed.

The crude death rate from tuberculosis is of course the first statistical fact to which we turn in studying conditions in a given community; and the differences, even in generally analogous areas, are surprisingly great. Thus, taking four eastern cities of roughly similar size, the mortality from all forms of tuberculosis for the period 1915-1919 was 199 per 100,000 in Providence and only 105 in Syracuse, with New Haven and Rochester lying between. The reason for such wide variations is difficult to discover, but is probably related to social and economic and racial factors of a complex kind.

As a measure of the efficiency of administrative control, the ratio of reported cases to deaths is a highly significant variable. In Rhode Island during the nine years from 1911 to 1919 there were 118 deaths for every 100 reported cases. In Massachusetts, on the other hand, for the period from 1906 to 1915 there were 72 deaths for each hundred reported cases, indicating nearly twice as full reporting.

In studying the tuberculosis clinic which is, in a way, the foundation of all tuberculosis work, statistical data as a rule are woefully lacking, outside of New York City, where the Association of Out-Patient Clinics has organized an admirable system of dispensary statistics. In most clinics, however, it is possible to obtain figures showing the total number of visits and the number of new patients received during a given period. Highly suggestive ratios can be obtained by comparing these figures with each other and with the population of the area which the clinic serves. The ratio of new patients per 1,000 population per year does not vary very widely. The highest figure noted in the Rhode Island study was 3.5 for New York City, the lowest, 1.7 for Woonsocket, R. I. The ratio of total visits per 1,000 population per year, on the other hand, was 20.8 for New York City against 3.6 for Woonsocket; and the ratio of total visits per new patient was 6.0 in New York, 2.0 in Woonsocket and 1.8 in Paw-

tucket, the figure for ordinarily well organized average clinics like those of Providence and New Haven being between 3.0 and 4.0. Many factors, such as the type of case receiving treatment, opportunities for sanatorium care, and the like, would of course affect this ratio. It seems probable, however, that the existence of a ratio of total visits to new patients below 3.0 pretty clearly indicates inefficiency in clinic administration, while a figure above 4.0 can only be attained by an organization which can hold its patients with unusual success.

In estimating the adequacy of nursing service, which is so important both in finding new patients and keeping old ones under supervision, similar ratios are highly significant. In well organized visiting nurse associations, like those of New Haven and Providence, 7 or 8 tuberculosis patients per 1,000 population are given nursing care, while in a group of small Rhode Island towns this figure fell to 2. The average number of visits per case ranges from 6 in East Providence to 16 in New Haven, and the number of visits to tuberculosis patients per 1,000 population per year varies from 19 in East Providence to 127 in New Haven (where there are nine tuberculosis nurses serving a population of 160,000 persons). The New Haven figures may be considered as representing almost ideal conditions.

Finally, the efficiency of machinery for sanatorium treatment may be studied from many different angles. The number of admissions to hospitals and sanatoria per year in relation to the number of deaths is the first standard which suggests itself. In Rhode Island the ratio of admissions per 100 annual deaths reaches the high value of 91, while in Connecticut it falls to 53. The extent

to which transfers from one institution to another may take place materially affects the value of this ratio. The average length of residence in the sanatorium is another important datum. Recently reported statistics range from 129 days at Wildwood Sanatorium to 269 days at Rutland. The factor of major importance in the whole problem is, however, the condition of the patient on admission—for it is this factor above all which determines whether sanatorium treatment shall succeed or fail.

We may close this over-long discussion by citing the results of studies of the after condition of discharged patients at two leading sanatoria which illustrate how and why the anti-tuberculosis program is failing to attain it ends. (Figs. I and II.)

Wallum Lake attains ultimate success in only 25 per cent of all the cases treated, while Gaylord Farm cures 44 per cent of its patients; and the primary reason is that but 5 per cent of all cases admitted at Wallum Lake are in the incipient stage, against 22 per cent at Gaylord Farm. The improvement of our nursing service, of our clinic organization, and of our general medical practice so that early tuberculosis may be detected and sanatorium

treatment given while there is time for it to operate,—these must be the primary objectives of the anti-tuberculosis movement if it is to reach its goal. EDITOR.

CARRYING DENTIST AND SURGEON TO A RURAL POPULATION

By JULE B. WARREN, RALEIGH, N. C.

TO COMBAT ill health in the mountain regions of North Carolina means to overcome the effects of illiteracy, ignorance, prejudice, and poverty. Physical examination, for instance, which discloses that a group of children are in need of tonsil or adenoid operations would of itself insure proper care of a very limited number of cases; for what knowledge of surgery is current among these mountain folk resolves itself into a prejudice against "cuttin' doctors." The approach is provided for, however, in the care of the school child. The teacher and the special Board of Health nurse, through organized health clubs which demonstrate the need, dissipate the unreasoning fear and opposition that may exist on the part of the parents, and prepare the way for the special neighborhood clinics through which Dr. G. M. Cooper, head of the Bureau of Medical Inspection of School Children, for the North Carolina State Board of Health, has brought the services of specialists to the farthest nook and corner of the state. The prices for these services are scaled down to the necessary minimum and provision is made for the payment of the major portion of the bill out of public funds. When this work was undertaken, it was not only a new experiment in the work of the North Carolina Board of Health, but the method was something new in this line of work in the whole country. Dental clinics had been established in a number of cities and states prior to the time the State Board of Health persuaded the North Carolina legislature that it was just as important for the state to care for the health of its children as it was to educate their minds; but the notable difference between the work in North Carolina and in other parts of the country is that in other places the free clinics have been paid for either by private subscription, or the money has been provided by the public, and only those who could qualify as charity patients were treated.

There is nothing new about medical inspection of school

children. The Empire of Japan has had a system of compulsory medical inspection of its school children by competent medical men for more than thirty years. The British empire after the Boer war instituted a system of medical inspection which was made country wide in 1907. In the United States the system has been of a patch-work nature. A number of the larger and more progressive cities of the United States have had fine systems of medical inspection for several years; but it was not made state wide until New York and Massachusetts enacted the laws requiring it several years ago. Even in these and other states which have passed the laws, the medical inspection does not reach the rural districts with the thoroughness that characterizes the North Carolina law, nor is the medical inspection of the children followed up with free treatment on any large scale except in North Carolina.

Since this particular bureau of medical inspection is doing a bit of pioneer work, a glance backward is interesting. The division of medical inspection for the state was organized by the North Carolina Board of Health in 1915, but the work was handicapped by the lack of funds with which to prosecute the plans. Dr. G. M. Cooper was brought to the Board from the county health work in the state and he immediately began to map out a system and to expand it. In 1917 the legislature passed the law which is really the basis of the present progressive program, and the next biennial session of the legislature gave the department of medical inspection enough funds to put free dental and surgical clinics for the rural districts, as well as for the cities, on a firm foundation.

Soon after Dr. Cooper took charge of the bureau work he came to the conclusion that medical inspection of school children in itself was but the means to an end, and that the basic defect of the system lay in the fact that it merely pointed out a trouble and made no provision for remedying it.

"It is pure irony to send the parent of four children in school, all of whom need dental treatment, a note stating the fact, when perhaps he lives twenty-five miles from a dentist and has no money with which to pay for the work, or to send the parent of a child a note requesting that he have the diseased tonsils of his child removed, when he may live a hundred miles from a specialist and does not have the price of a railroad ticket," Dr. Cooper said recently in discussing this phase of medical inspection as it was in North Carolina.

After working on medical inspection of school children for a short time, Dr. Cooper found school teachers sending in hundreds of reports from every county in the state in which it was shown that there were thousands of children whose teeth needed attention, and who had bad throats or diseased nasal organs. He found the teachers, who are the nucleus of the inspection system under the North Carolina law, intensely interested in the work of correction as were the parents in most instances, but it was impossible to get the work done in the rural districts where dentists were scarce and there were no specialists

Outdoor work was done in Bender County. The teeth of 543 children were treated in a district that could boast only one dentist to fifteen thousand people.

at all. The bureau head made an effort to interest hospitals and other institutions in this work, but always found such institutions willing to do the work without charge only on condition that the cases come to them as charity. Many of the families involved were not dependent on charity and did not want to be put in that class. Even if that objection to the old system could be overcome it was impossible to get the work done on as large a scale as the needs demanded. The problem resolved itself down to these two propositions: (1) Getting the dentists and specialists for the work and getting them to the people; and (2) Getting the money from public funds with which to carry on the work.

The first of these problems was met by the establishment of traveling dental clinics and temporary hospitals for operations on throat and nose in the rural districts. This was the program mapped out by Dr. Cooper, but it was a program that would take money and lots of it, for the originator of the idea was determined that the work should not be done on a charity basis. He believed the state should assume the responsibility for treating these children. Here is the way Dr. Cooper feels about charity work as expressed in a statement he issued for one of the health department publications about the time the whole issue was up for consideration:

No zygodactyl bird of the order Psittaci ever told himself 'Pretty Polly' with more satisfaction than otherwise responsible people derive from mouthing 'Not able to pay.' It is unction to their souls. It is balm for many a troubled conscience. 'Oh, yes, this hospital offers free treatment to those who are not able to pay,' says the

president of the board of visitors, adding, of course, 'except a small fee to take care of incidentals.'

'Special provision for those who are not able to pay'; 'the worthy poor'; 'for charity,' are a few of the canting generalities which cover a multitude of the sins of omission. The North Carolina State Board of Health is neither Bolshevik nor Prussian; nor is its mission the setting of a wrong world right; but some of us who have played the game of life in the rough—who have practised medicine and occasionally ourselves have bound up a wound, as well as sat on the 'rail' and watched the big men operate—have so often been balked in a sincere attempt to render honest service by the trite satisfied reply, 'Oh, yes, if he is not able to pay,' that we have become convinced that the expression itself is a howling hypocrite.

Suffering humanity means just exactly nothing to us, but suffering individuals, whom it is partly our duty to assist, mean everything. This peculiarly applies to the correction of the common physical defects of thousands of school children in North Carolina.

Convinced of the need of this type of work among the school children of the state after a personal examination, together with a direct supervision of the examination of 200,000 children in the public schools, Dr. Cooper began the experiment with free traveling dentists in Nash County, N. C., in July, 1918, and since that time the work has been extended to twenty-five other counties both for dental and surgical work among the rural school children.

Plan Proved Practicable

The records of the examination of the 200,000 children showed that 75 per cent of them had beginning decay in permanent teeth. Less than 10 per cent of the children had ever visited a dentist's office, and at least ninety out of every hundred parents had never made an effort to have the children's teeth looked after.

The neglect was found to be due to several causes: (1) Poverty; (2) ignorance and indifference; (3) morbid fear of the dentist; (4) hesitancy of many dentists to accept young children as patients; and (5) lack of specific instruction in the public school curriculum on the care of the teeth.

Notwithstanding the apparent need and the seeming practicability of the plan, the work was undertaken with some misgivings as to the results. The plans were laid before the annual meeting of the state dental society. Dr. Cooper did not know how the dental profession would feel about it if the state took up the paternalistic work of furnishing free treatment to the large number of school children in the state. There were no grounds for fear that the dentists would feel that the state was taking a living from them by giving free dental treatment to the children; on the contrary, when the matter was presented to the annual convention of the dentists in June, 1918, the following resolution was unanimously adopted:

Resolved: That the North Carolina Dental Society heartily endorses the plan of the state board of health, as outlined by Dr. G. M. Cooper, and that we pledge him the loyal support of this society.

The North Carolina society is forty years old and embraces 80 per cent of the dentists of the state, including the leading members of the profession. It is to the credit of the organization that every member has lived up to the spirit and the letter of that pledge. This applies to all dentists in every county, with one exception so far covered. One dentist in one of the counties took the pains to inform all who listened that "to work on the teeth of children under twelve years of age would bring on diseases." Just what diseases, he was, of course, careful not to state, and that dentist, it may be said, was not a member of the state society.

In the work as it has been developed for the rural

talks over the situation with the teacher and then visits the parents of the children who show physical defect. She prepares the way for the coming of the dentist, who is employed in most instances by the board of health and sent to a county to remain until he completes the job.

These dentists carry a portable dental apparatus with foot engine and such other essentials as are needed for the cleaning and extraction of teeth and for making permanent amalgam fillings. He sets up his portable office anywhere it is most convenient. The school porch is often used, the shady side of the school building in the summer time, or he may utilize the cloak room of the school house in bad weather. The doctor begins work when school opens, or before, and keeps on until late in the afternoon, taking the children as their turn comes. After the first few children have passed through the ordeal the others are anxious to leave their studies for the session with the dentist. All the time the work is being done the dentist or the nurse gives the children instruction on the proper care of the teeth. Tooth brush drills are held and prophylactic work is done during the stay of the dentist in the community.

The Plan is Elastic

When all the children in one rural school have been treated, the dentist packs up his folding chair and moves on to new fields. He keeps the work up until all the children from six to twelve years of age in the county have been reached, and is then moved to some other county where similar clinics are conducted. While this has been the general plan for holding the clinics, variations were often found necessary, and under these circumstances the plan is elastic enough to permit any changes that local conditions may demand. If the dentist found that the rush of work was such that it was impossible for him to do all the filling needed by every child, all teeth are cleaned and the bad ones extracted and at least one permanent amalgam filling placed where it was most needed. The child's parents are then advised to go to some local dentist for the remainder of the work. If the traveling dentist was working in a rural and mountainous county where dentists were not to be found except by circuitous and long trips to neighboring cities, he simply remained on the job until all the children had been treated.

During the first year of this work 6,678 school children in North Carolina were treated at a cost that ran from thirty cents per child to \$1.10 per child, or an average of about fifty cents for every patient treated. It is

communities in North Carolina, the first job is the medical inspection required by law. The school teachers do this under the direct supervision of Dr. Cooper. The individual report card for every child is forwarded to the state Board of Health, in whose office the compilations are made. Bad teeth, bad throats, poor eyesight, and other defects of childhood which the teacher can easily ascertain are noted on the cards. Following this, one of the nurses of the board of health makes a visit to the rural schools,

estimated that the parents whose children received this treatment during the first year were saved at least fifteen thousand dollars in dental bills. The whole attitude of the rural population toward dentists and toward the importance of oral hygiene is being revolutionized as a result of this work. Some of the letters from young men the board of health sent to the rural communities interestingly, though unconsciously, reveal this changed attitude.

Here are extracts from the letter a conductor of a clinic in Robeson county wrote while he was in the midst of the work of treating more than fourteen hundred children:

The people here are certainly responding to this work and I am taking the keenest delight in it myself. Of course, this movement can't be anything short of a great success, the worth of which can never be expressed in figures and statistics. To think of the enormous number of sixth year molars that I know I have saved already, knowing their worth, and knowing that they would otherwise have been lost, emphasizes but one aspect of the importance of this work. . . .

Now a little more about my work here. My office hours are from early morning till late in the evening, and at that I often have to see disappointed children go home, not being able to get to them that day. And they are nearly always back on the job next morning. With children there from such great distances and needing attention so much, I can't set any time limits on my operating hours. . . . Our proposition here is not getting the children to come, but in trying to limit their attendance to near the number I can treat in a day.

This letter is typical of the many that have come from both doctors and nurses and from the people themselves. In practically every county where the work has been done so far there have been more children asking for treatment than one doctor could handle properly. People have walked to these clinics from miles away. They have come in automobiles, ox carts, buggies, wagons, and not a few of the mountain people have come in from great distances on foot. Grandmothers who have never before seen a dentist, but who have come to their grandmotherhood through the various stages of toothache to toothlessness, have brought their grandchildren to the tooth "doctor" in order to have them treated. Old and young, men and women, black and white, have been given instruction in the importance of oral hygiene and in the care of the teeth. That the seed of information has fallen on good soil is indicated by the increased sale of tooth brushes, tooth paste, and other dental preparations in every lo-

cality where the traveling dentists have worked. And the business of local dentists in nearby towns has been increased because the knowledge of the dangers coming from decayed teeth sends the older people to the practitioners in the settlements and towns.

Precedes Permanent Work

One of the most important results of these free dental clinics paid for out of funds provided by the state, the county, and, in some instances, the International Health Board—the state paying more than 90 per cent of the bill—has been an aroused public interest in dental work for school children. This new interest is shown in the fact that some of the wealthier counties, which have full time health departments, have established free clinics of their own. This has been done in half a dozen counties already and others are getting ready for the work. The state aids in the payment of the dentist the first year and helps secure a man. After that the county pays the bill for the free dental office the year round, where school children of the county, rich and poor alike, may get free dental treatment at any time they make the arrangements with the dentist.

The medical inspection of school children revealed that in addition to those who had badly decayed teeth there were many who had diseased tonsils and adenoids. Of this latter class, 75 per cent or more were unable to go to a specialist, both because of the cost and because of their inaccessibility. This presented a much more serious problem for the Bureau of Medical Inspection, but the plan finally adopted has worked so well that since it was inaugurated more than thirteen hundred children have undergone operations by specialists provided for by the state Board of Health.

Adenoid and Tonsil Clubs

Dr. Cooper and his helpers, with the aid of school teachers, form "Adenoid and Tonsil Clubs" in a number of the districts where these troubles are present in sufficient number to justify bringing a specialist from some city in the state to the rural community. The school nurses instruct the parents about the dangers of these diseases and encourage them to sign the cards for the clubs. When a sufficient number of children are secured for one of these clubs, arrangements are made for holding the clinic. A maximum fee of \$12.50 is charged for these operations, which is considerably less than 50 per cent

The big white schoolhouse that sits on a hill in Macon County, back in the mountains. The dentist is at work, and the mountain children are there from miles around for inspection and care.

of the average fee for such operations in private practice. Provision is also made for the operation on some children without fee. In such cases the school nurse, the teacher, and the head of the department find out home conditions of children and simply make no charges for such operations, although the fact is not generally known among others who join the club.

The most eminent specialists in the state have been interested in this work from the very beginning. Arrangements were made to pay them a reasonable amount for their services—payment being made by the day and not by the case—and these men have been commandeered for a day or for several days to perform the operations on children concentrated at the temporary hospitals by the Board of Health workers. Here is a description of the way one of these clinics is conducted, as told by Dr. Cooper:

We fit out some place like an armory, or any building capable of being heated and lighted properly, where quiet and privacy may be had. The equipment consists of cots, sheets, blankets, towels, pus pans, hot water bottles, and such other necessary equipment as would be found in an emergency hospital. An extra room is fitted with a table to be used as an operating table, and a heater for sterilizing instruments is provided. All of this equipment is furnished by the State Board of Health, is the property of the Board and, when not in use, is shipped back to general headquarters, where it is kept as a portable hospital unit.

The children are required to come to the clinic without breakfast, and are put to bed after a final examination by the specialist. The operations are all done for the day for as many children as the operator may be able to take care of. The number done in one day by one man has varied from nine to twenty-three. The children are put to bed in the emergency hospital immediately after the operation and a trained nurse remains with them all night. As a rule, they are all able to go home on the day following the operation. Under no circumstances are they allowed to go home until the day after the operation. This rule is fixed, positive, and from it there is no appeal. If the child's parents will not allow it to remain in the emergency hospital the night after the operation, its case will not be accepted for the clinic; for the Board of Health will not assume responsibility for the operation if it does not have the opportunity of seeing that it gets the proper treatment immediately afterwards, or until there is no longer danger of complications.

The specialists are employed for the work by the day or by the trip, are paid by representatives of the Board of Health and have no worry or bother with the collection of the fees. When the clinic is over, they return to their homes having performed two, three, and sometimes four times as many operations for the fee as they would perform in private practice for the same money, but

rejoicing in the fact that they have accomplished some real good.

"Bargain counter surgery" some of the few critics of the plan have called it; but the critics have been few and far between, for the success of the plan has more than justified the hopes of those who were responsible for its inauguration. Through it, a large number of children who could never get the benefit to be derived from the major operation necessary for the removal of tonsils or adenoids, have these troubles removed and are put on a par with other healthy children of the state. Through the working of the plan, 2,154 children in thirty-three counties of North Carolina have been operated on during the past twenty-two months. The operations in practically every instance have been highly successful, and with but few troublesome hemorrhages after the operation, and no complications. Only one death has resulted. That from local anesthetic in a patient, a fourteen year old girl, who had goiter.

Considered purely from the standpoint of finances, the conduct of these clinics in North Carolina has been a good money investment for the state. Had the twenty-one hundred operations been performed—and bear in mind the vast majority of them would not have been performed—in a hospital and paid for by private funds, it would have cost the parents of the children not less than \$135,000. As it was, the twenty-one hundred paid

approximately \$21,000 for the work. The state, of course, made an outlay of money; but the results have been well worth while, for the small investment by the state has resulted in a 600 per cent saving to the parents who had sick children, and has made it possible for these twenty-one hundred sick children to become well. Their tremendous physical handicap has been removed, and they have been put on an equal footing with the other children of the state. They will be able to learn more in school and their economic value to the state has been very much increased.

In addition to the economic value of this work already done, the experiments carried on by Dr. Cooper in putting this type of public health work on a permanent footing have opened up an entirely new field for public health service. The North Carolina board has been a pioneer in this work and has proved beyond the shadow of a doubt the efficacy of its method of handling this big job of solving the problem presented by the medical inspection of school children. Dr. Cooper, the Board of Health, and the legislators, who caught the vision presented by Dr. Cooper, believe the country generally will work out this proposition on the basis that the state owes the child the opportunity to improve its physical condition just as much as it owes it the opportunity to improve its mental condition. Compulsory health practice may one day parallel and serve to make more effectual our compulsory education.

THE TYPHUS SITUATION

THE following authoritative statement from Surgeon General Cumming has been issued in regard to the typhus situation growing out of the discovery of typhus aboard vessels carrying immigrants to the United States.

The menace to this country from the introduction of typhus from Europe is not of recent development and is no greater today than it was six months ago. Even before the armistice the Surgeon General recognized the potentialities of the disease spreading to the United States if adequate precautionary measures were not taken when immigration was resumed. During the past year medical officers of the Public Health Service have been stationed at American Consulates at chief European ports of embarkation to supervise measures to be applied against ships and passengers for the prevention of the spread not only of typhus but also of plague and cholera. While the measures enforced at the European ports have by no means been perfect, their value is indicated in the fact that several hundred thousand immigrants have come from typhus infected areas on several hundred ships and that out of all this number, typhus infection occurred only on eight vessels. With the exception of the steamship *President Wilson*, which arrived at New York on February 1, infection on the ships was detected by the quarantine officer at New York and effective precautionary measures applied. Upon arrival of the steamship *President Wilson* at New York there were three cases in the sick bay of what the quarantine officers diagnosed as bronchopneumonia, but which later on proved to be typhus. The doctor was experienced in the detection of typhus, but the cases presented no eruption and the mistake was by no means inexcusable. Still under the custodial care of the immigration authorities, the sick people were sent to the Long Island College Hospital, which takes care of sick immigrants, and the correct diagnosis later became apparent. Fortunately, the error was dis-

covered before the other passengers in the steerage were released, and the vessel and the immigrants were remanded to quarantine and appropriate treatment applied to prevent the spread of the infection. The incident was unquestionably deplorable, but it indicated neither a breakdown of the New York quarantine station nor any unreasonable laxity.

The system of quarantine protection developed by the Public Health Service consists of a double line of defense, first the medical officers at foreign ports who supervise preventive measures specified in the United States Quarantine Regulations, and, second, the facilities at United States quarantine stations. If infection evades the first barrier, the ship still has to undergo inspection and treatment at her American port of arrival.

Several weeks before the arrival of the steamship *President Wilson*, the Surgeon General had taken very definite steps to strengthen the quarantine defense at European ports by having American consular officials instructed, through the State Department, to withhold bills of health from vessels whose passengers had not been satisfactorily disinfected. As early as January 17, quarantine officers at Atlantic ports were advised that on account of the unsatisfactory delousing procedure carried out at Danzig, all passengers arriving at their ports should be held in quarantine and

The most dreaded of fevers, Typhus, is the object of especial care at ports of entry of immigrants from the centers of the infection.

treated for the destruction of vermin. It must, therefore, be evident to any fair minded person that the Federal health authorities have been most diligent in carrying out anti-typhus measures, and that any statement that either the federal health service or the state officials of New York have been derelict or indifferent to the typhus situation is obviously untrue. Nevertheless, administrative efforts of this sort cannot be expected to be perfect or to eliminate mistakes by individual officials.

Typhus is not transmitted by lice in general, but only by lice that have previously bitten persons infected with typhus. A louse is by no means an exotic insect, as one might infer by some recent press interviews. It is widespread throughout the United States, but is found chiefly in the slum districts of large cities. In the absence of typhus it is of no sanitary significance or danger so far as the present situation is concerned. Typhus fever develops in four to twelve days, and if cases do not develop within this period it can safely be asserted that the infection is not present. This applies particularly to overseas vessels that have been out twelve days or more.

International.
This is not a Ku Klux Klanner in his white robes, but a New York health inspector equipped to inspect the baggage of an immigrant.

Much confusion has resulted from the statements in newspaper interviews in New York City as to responsibility of the Immigration Service at Ellis Island for the exclusion of typhus fever. Immigration officials are not vested with any authority administering quarantine laws. Furthermore, they have no equipment for enforcing quarantine measures; naturally so because they have control over aliens and not over citizens of the United States,

although the latter returning from Europe are just as serious a menace from the typhus standpoint as is an alien. It is true that Ellis Island has always proved a valuable line of second defense for the port, but the responsibility for the exclusion of typhus and other quarantinable diseases rests solely upon the quarantine authorities. As a matter of ordinary decency and personal

Searchlight is thrown upon the agent that carries typhus. Twenty-eight out of 550 persons inspected were found to be infested with vermin.

hygiene, delousing facilities should be provided at Ellis Island, but since the prevention of the introduction of typhus relates to returning citizens as well as aliens, the quarantine station is the one place where effective preventive measures can be carried out.

THE HEALTH OF THE TEACHER

The *Lancet* (London) of February 5, 1921, makes comparison between the health of teachers, as a class, in America and in England, quoting the results of an inquiry by Ralph Wager of the Department of Biology of the Northern Illinois State Normal School regarding the health of teachers, and the findings Dr. William Oldwright, of the Department of Hygiene in Toronto University, the former finding a high incidence of remediable defects, and the latter an inordinately high tuberculosis rate among teachers.

Teachers in England are a selected class, examination as to physical fitness being required prior to training, so that remediable defects are corrected and there is a weeding out of the unfit. Nevertheless, in England the mortality of the male school teacher under forty-five years of age appears to be below the standard, and the incidence of tuberculosis is very high, considering that these lives are selected on a health standard.

Dr. Hans Meirhofer found that in Zurich during the years 1912-14 found an equally unsatisfactory condition among teachers, the preponderance of maladies being nervous and respiratory affections. Dr. E. S. Yonge found pathologic throat conditions in 70 per cent of one hundred teachers examined in Manchester.

The remedy, says the *Lancet*, lies not only in a more rigid adherence to the comprehensive hygiene syllabus now required in English training colleges, but conditions of pay need to be revised, and the conditions of monotonous drudgery in unhygienic conditions need to have such attention as will render the teaching profession a more attractive one all round.

STANDARDS AND METHODS FOR HEALTH WORK AMONG CHILDREN OF PRE-SCHOOL AGE*

By ROBERT D. CURTIS, M.D., BOSTON, MASS.

THE necessity for the continued supervision of the child beyond the age of infancy has been discussed at sufficient length to convince us all of its importance, and we are now confronted with the problem of developing a workable scheme for putting our convictions into practice. Infant welfare work has reached such a degree of development that procedure is relatively standardized, and information covering most of the phases of that branch of preventive medicine may be obtained from a number of books and periodicals and by observation of the working of a number of well established associations. Such sources of information with regard to work among children of pre-school age are not available. Given the case of a single child between one and five years of age, we are able confidently to make recommendations which we feel will put him in the best possible physical condition and maintain him there. With regard to the proper procedure with large groups of children, however, we are still uncertain.

We are engaged in developing a branch of preventive medicine which, from our present viewpoint, is the only unforged link in the chain of supervision that under ideal conditions should safeguard the welfare of the individual from the time of conception until death. Many of the links are as yet imperfect, but, beginning with prenatal care and extending through infant and child welfare, school hygiene, protection for the adult at work, at home and at play, to provision for the aged, the care of the child of pre-school age is the least well covered field.

The realization that it is our task to create rather than to copy should be a sufficient incentive for our best efforts, and this article is presented with the intention of offering suggestions in that field. Some of them are the result of experience in child welfare work, while others, unfortunately, have no such background to recommend them; but I shall not on that account hesitate to express them in dogmatic fashion. Even though they may later prove to be impracticable, they should at least serve as starting points for discussion. Further progress in this phase of work awaits crystallization of opinion on what to do and how it should be done.

Childhood may be considered to begin with weaning from the breast. Having passed through the dangers of infancy with the protection against environment afforded by his mother's milk, that protection is suddenly withdrawn, and the child faces a new group of dangers dependent on his increased activity and the new relations with his surroundings. After the period of breast feed-

The weakest link in schemes designed to provide continuous health supervision for all the people all the time has been the period where infant welfare leaves off and school hygiene begins. The Child Health Conference fills this gap.

It is a noteworthy observation that in children regularly "graduated" from the infant welfare departments there is a marked diminution in the average incidence of physical handicap, which makes possible positive health promotion work.

It is here, then, that preventive measures may really become effectual. Whatever of intelligence and adaptability the child may acquire depends largely upon environmental conditions during this plastic period. Therefore it behooves us by all legitimate means to arouse the parents, interest the children, and prepare the workers to cooperate in a constructive health program.

ing, environment assumes a greater importance and our area of supervision is proportionately widened. It is not enough to repair teeth, remove diseased tonsils, and rearrange the family budget to provide an adequate diet. We must insure that the back alley playground is free from refuse; that the nearly convalescent from diphtheria maintains quarantine; we may be required to take steps to investigate the ice cream vendor's cart, or insure that the father, who is a metal grinder, is protected from emery dust at his work.

Theoretically the ramifications of clues afforded by a single family would, if followed to their conclusion, result in an investigation of all human activities. Without attempting to discuss so Utopian a condition, we must bear in mind the fact that anything which affects the family for good or for evil has a corresponding effect upon the child. Supervision of the child requires close cooperation between various sorts of agencies, with the resultant danger of overlapping of effort and the wasting of time in investigation. This danger has been lessened by the development of the "confidential exchange," a central bureau where properly qualified persons may obtain the results of investigation by the various agencies which have already been interested. Without so convenient a means of checking up and correlating activities, waste of time and money is bound to occur.

Pre-School Conferences Urged

We who make preventive medicine our profession have been many years in coming to a realization of the importance of pre-school age supervision, and it is expecting too much of the average mother, whose horizon is bounded by domestic duties, to have as clear a vision as our own as to her children's need for supervision. Through education and because of a healthy fear of depending on her own judgment, she seeks our advice with regard to her infant; but when infancy is past she feels entirely competent to deal with the every-day situations which concern her child. The situation is complicated by the fact that there is frequently at this time another infant who demands the greater part of her attention. The mother seems never to feel competent to trust entirely to her own judgment in dealing with her infant, whether it is her first or the latest of many. There is, consequently, no problem to maintaining the attendance at baby conferences. This, however, is not the case with conferences for older children, who are seldom brought to the conference spontaneously unless they show some obvious physical defects. Out of a great many children, I can recall hardly an instance where the mother has, of her own volition, brought her supposedly normal child for supervision.

*Read before the Eleventh Annual Meeting of the American Child Hygiene Association, St. Louis, Mo., October 11-13, 1920.

If our conferences are to be well attended, we must devise means for inducing parents and others to send children to us. This can best be brought about by education of the community to the value of our work. This means, first, the education of the mother. Under ideal conditions all of the children of the older age would come to us as graduates of an infant welfare conference, and this imposes on the doctor and nurse of the infant conference an obligation to make sure that by the time the baby has reached the end of infancy he is ready, not for discharge, but for graduation to the conference for older children. The infant conference is our greatest opportunity for the education of mothers, for they have learned to look to us for advice, and to accept it with the assurance that it is valuable. Other members of the community, nurses, social workers, charitable organizations, hospitals, dental clinics, also need instruction before they will realize the value of sending well children for supervision. Widespread advertising, weighing and measuring campaigns, and "drives" for funds, are temporary expedients which lend impetus to a new organization and help to speed up one which is lagging, but their effect is only temporary, and they cannot have the far reaching results of an orderly and well planned scheme of community education.

The Well Child Neglected

I feel confident that medical and social workers can readily be made to see the value of our work, and that they will cooperate accordingly; but observation bears out the statement that a great many, if not most, mothers will not be satisfied to bring their apparently well children to a conference merely for a physical examination and the advice that they should be taken to a dentist or a nose and throat clinic. There must be some activity in connection with the conference which will appeal to the mother as being of definite value to her child. This is a part of her education. If we adhere closely to our principle of doing purely preventive work, our choice of such an activity is limited. Tonsillectomy, adenoidectomy, and the repair of dental defects, are therapeutic measures closely related to our work; but they are, strictly considered, adjuncts. Vaccination, dental hygiene, and the maintenance of posture classes are preventive functions. Vaccination is usually under the direction of the local board of health, and is properly a function of that body. Its performance adds to the work of the conference doctor, whose time can be more efficiently applied, making it an undesirable activity in connection with our work. Dental hygiene may be made to exert a universal appeal, and its value to the community has been proved by the work done at Bridgeport, Conn. This is a desirable activity. Faulty postures of slight degree are the precursors of serious deformities in later life, but are seldom given the attention they deserve in a busy hospital clinics where more evident deformities abound. For our purpose I feel that their correction may be considered a preventive measure, and I am sure of the appeal which the posture class makes to the parents. With the establishment of dental hygiene and posture classes in connection with our stations, we can give each child something of definite value which can hardly fail to be appreciated and desired by the parents, and still limit ourselves to preventive work. Children of pre-school age are capable of being readily trained to cooperate in this sort of work if they are properly handled.

If, after convincing the mother that it is a desirable thing further to bring her child to the conference, we fail to consider the child's point of view, we shall still

have difficulty in getting him to come. The mother's viewpoint is partly a reflection of her child's and, if he finds nothing at the conference which makes it seem worth while to come again, he can object in so effective a manner that the mother will give up the struggle. During the period of waiting for examination, the services of a story teller, picture books, toys, and possibly a sand box, keep the children in good humor and make it much easier for the doctor to do his best work.

Personnel of Conference Varied

There are several practical differences between the operation of conferences for infants and those for children. For the infant conference a single good sized room is often sufficient, but for the children's conference a separate examining room is necessary, since many of the mothers find it distasteful to have the defects of their children pointed out in public.

The doctor needs a special adaptability for dealing with children in regard to both training and personality. His recommendations for treatment and supervision are drawn largely from his own resources, for there are no available sources of reference for his problems, and the success of the conference depends in a large measure on his personality and his ability to maintain pleasant relations with the children. He must constantly keep in mind that the child's cooperation both in the conference and in the home is requisite to success, and that it can be secured only by unfailing honesty, truthfulness and kindness. A physician's gruff, offhand manner in an infant conference may deter a small number of mothers, but in the children's conference it results in no attendance in a surprisingly short time.

The physical examination of children is a relatively more important and more prolonged procedure than the physical examination of infants, and correspondingly fewer patients can be examined at a conference. During the usual two hour period from twenty-five to thirty infants can be examined with a reasonable amount of individual attention; but the examination of ten to fifteen older children occupies the same length of time. Examination of a well child should be done once in three months, and the examination of those below normal as often as is necessary.

During the conference the dietitian, or nurse, should be free to spend her time with the doctor, while an assistant—usually a volunteer—looks up records and supervises the undressing and weighing. A second person to interest the children by story-telling or playing games is of great assistance. In the Boston Baby Hygiene Association, we have made use of college students taking a household economics course and have found them very helpful. They are assigned to the conference as a part of their course, and are given a small number of families to supervise. Volunteers from a training school for kindergarten teachers have been used as story-tellers and play directors. The personnel of our conference, then, consists of a doctor, a nurse (or dietitian), a nurse's assistant, and a play director.

Must Develop Preventive Workers

Under the present method of training preventive workers it is to be questioned whether the conference for older children should be in the charge of a dietitian or of a nurse. Considered from the viewpoint of efficiency, it is evident that if the nurse who has taken care of the infant continues the supervision through childhood, a considerable saving in time will be effected by making it unnecessary for a second person to win the confidence of the family and become acquainted with its social problems.

The supervision of the younger and older children of the same family by different persons is certainly a duplication of effort. With supervision continued after infancy the amount of work to be done by a welfare association increases at a surprising rate, making measures for greater efficiency correspondingly more necessary.

The training of the average dietitian is deficient in that she is unable to detect abnormal physical and hygienic conditions which are obvious to the nurse. The results of a physical examination frequently mean little more to her than a list of diagnoses whose significance she cannot quite grasp, and her management of these cases in the home is controlled by blindly following the doctor's instruction after the fashion of a conscientious, but untrained mother. She must of necessity neglect many opportunities for service because of her inability to recognize them. She has, however, a training in the management of the more complicated social problems of childhood and in the handling of difficult dietary problems, which the nurse lacks. In short, neither the nurse nor the dietitian, as trained at present, is entirely competent to supervise children from infancy to school age. If we are to have a single person take charge in both types of work we shall have to secure for her a broader education than is now given to either the nurse or the dietitian.

Accessory Clinics Helpful

The number of physically defective children encountered in public schools is a measure of our laxity in child welfare work, and a classification of their defects may be used as a guide in determining what types of preventive work are most needed during the pre-school period. The following are the commonest defects found on examination of twenty million school children: Mental defects, 1 per cent; tuberculosis, now or in the past, 5 per cent; defective hearing, 5 per cent; defective sight, 25 per cent; diseased tonsils or adenoids, 15 to 25 per cent; deformed feet, spine, or joints, 10 to 20 per cent; defective teeth, 50 to 75 per cent; malnutrition, 15 to 25 per cent.

We have, then, to consider the following types of work:

(1) *Psychopathic*.—Except for a rare case of evident feeble-mindedness, few children of this age show a sufficient degree of mental defect to raise the question of their being sent to special schools. Occasionally, however, subnormal mentality is suspected from the knowledge of the parents, and in such a case expert opinion is helpful in giving us assurance that we are justified in handling the child as one of defective mentality.

(2) *Tuberculosis*.—Clinically active tuberculosis is also relatively rare. Infants who contract tuberculosis usually fail to reach the pre-school age and, while doubtless many children contract the disease between the ages of one and five years, it has seldom progressed far enough to be evident except on a most careful physical examination. That fact makes it important that the services of an expert should be available to pass on doubtful cases and those which have suffered known exposure. It is difficult to decide whether to be pleased or concerned over the small number of children who present a positive diagnosis. If, as has been maintained, a large proportion of initial infections occur in childhood, cooperation with a tuberculosis clinic is of first importance.

(3) *Eyes*.—Defects of vision, except those of marked degree and those resulting from corneal scars produced by an old keratitis, are seldom encountered. Visual defects begin to be evident after the child has entered school and may, except in isolated cases, be left to the school physician.

(4) *Ear, nose, and throat*.—From the above table we

find that from 15 to 25 per cent of school children have diseased adenoids or tonsils, and that 5 per cent have defective hearing. The latter defect, like defective vision, is usually discovered at school; but, unlike defective vision, its prevention in many cases is within our province through the removal of diseased adenoids. The treatment of conditions of the nasopharynx is one of the most important parts of our work, and its value is not to be minimized. The removal of hypertrophied adenoids is a very frequent and a very necessary procedure, but the criticism that has been applied to unnecessary tonsillectomy in private practice is equally applicable in our work. The removal of tonsils as a shot in the dark to improve the condition of a child who is below standard, may do more harm than good, and should be done only after serious consideration, no matter how great may be the desire to do something tangible. It must be conceded that the number of harmless tonsils we remove far exceeds the number of diseased ones that we leave in place. We should, however, have provision for the prompt treatment of these conditions when it is indicated.

(5) *Orthopedics*.—Deformities of the bones, spine, and joints are relatively frequent. A few are congenital in origin, but the majority are the result of rickets and of faulty nutrition. The latter class is another measure of the inadequacy of earlier supervision. It is a noteworthy sign of progress that these deformities practically do not exist among children who were under the supervision of an infant station during their first year. Their prevention is distinctly our individual problem, but under present conditions many of them are well established, and these as well as the cases of congenital origin require the service of an orthopedic clinic.

(6) *Teeth*.—Dental caries is by far the most prevalent defect found in children of all ages, and the dental clinic occupies an important place in our work. Here again the problem is partly concerned with infant supervision and the prevention of rickets. Rickets lowers the calcium metabolism just at the time when the permanent teeth, although unerupted, are forming their enamel. The first dentition is rarely defective except as a consequence of neglect; proper dental hygiene during the year before school, combined with whatever dental treatment may be necessary, should insure the preservation of the first teeth until their function has been accomplished, thereby avoiding the evil results of focal infection and malocclusion. The greater frequency of diseased tonsils in the presence of carious teeth is of itself sufficient reason for preserving the first dentition in good condition.

(7) *Nutrition*.—Improper diets are nearly as common as carious teeth. In many cases malnutrition is the expression of the effects of disease and readily disappears when concomitant diseased conditions have been corrected. There is in addition a class of cases where malnutrition may be considered as an entity, not dependent on other abnormal physical conditions. Under such circumstances the remedy is entirely dietary, and the services of an expert dietitian are needed to outline a suitable diet and to assist in rearranging the family budget so that proper foods may be purchased.

To sum up the phases which may be regarded as essential to our work, they are a tuberculosis clinic, an ear, nose and throat clinic, an orthopedic clinic, a dental clinic, and a nutrition worker. Even with these facilities we shall find occasional children who are subnormal, and who fail to show improvement under the closest supervision. In such cases a complete change of environment, if only for a week or two, will often give the needed impetus, and save months in getting the children into

proper condition. It is desirable, therefore, to have some means for providing a change of scene for this type. It is not always possible to maintain a farm or a camp at the seashore, but arrangements may often be made with a trustworthy family to care for a child during a short period, either for a small sum or for the expense of his maintenance.

Mental Hygiene Also Important

Supervision of the child's physical welfare is our most obvious function, but through our close association with the mother in the conferences and in the homes we should take advantage of the many opportunities for the direction of mental hygiene and help to prepare the child for contact with his fellows by directing play and teaching discipline and the beginnings of work.

Clinics such as I have mentioned are usually available wherever there is a general hospital and, except for the nutrition work, are not a part of the welfare association. Most communities have also arrangements for taking care of cases of the acute infectious diseases when they cannot be properly isolated at home. When a child contracts measles, scarlet fever, or diphtheria, he may be cared for in the hospital, but, should he have whooping-cough, he is treated as a pariah by both physicians and laymen. This disease has a mortality of about 25 per cent during infancy, and is far more fatal at that time than is any other of the acute infectious diseases. Its mortality decreases considerably after the second year, but it is still a serious disease whose spread among the infants is dependent largely on child carriers. After the diagnosis of pertussis has been made it is the custom of most hospital out-patient clinics to refuse admittance again until the patient has entirely recovered. This one of the infectious diseases which carries the greatest mortality during infancy is allowed to go absolutely untreated. If, as most of us believe, there is value in the administration of pertussis vaccine, it should be made available to all children by the establishment of special clinics.

Transportation of children from homes to hospital clinics is often difficult to arrange, and requires the services of a worker whose time could be better spent in less routine work. The trip to the hospital can be made attractive to the children and the services of a trained worker spared by cooperation with a volunteer motor corps.

Size of District Covered

The size of a district that can be effectively covered from a single station will, of course, vary with the density of the population. We have found that the maximum number of either infants or children that can be supervised with efficiency by a single worker is 175. Figuring on this basis, we may assume that if a single worker is to supervise a group of children from birth to five years, her maximum registration will be 175. If this number of children is evenly divided among groups of increasing age, we may expect 20 per cent of them to reach the age limit each year. On this basis the worker will be able to take on thirty-five new infants a year to supplant the children who have gone to school. It is impossible with our present meager data to set down a fixed rate of turnover for this work, for the birth and death rate vary considerably according to living conditions, nationality, etc. We should, however, be able to give each worker a fairly even age distribution in her group, since the number of families where there are two or three children under the age of five is about equal to the number of families where there is a single infant.

The supervision of our older children, as well as infants, results in the very rapid growth of an organization during the first years of the new arrangement. Without considering the normal yearly growth of an infant welfare station, the extension of care to the age of five years means that the registration will be doubled during the second year, trebled during the third year, and quadrupled during the fourth year. This does not necessarily entail a fourfold increase of all expenses, for the stations and part of the apparatus will serve for both types of conference. It does, however, mean fourfold increase in the number of workers, whose salaries are our greatest item of expense, and an increased expenditure for supplies. Few associations, however well organized, can meet such an increased expenditure, for most of us find that our present rate of growth is limited by our income. It will be necessary, then, either to spread our extended supervision thinly over a number of stations, or to limit the supervision of older children to a few stations, extending the work as our resources allow. From the standpoint of immediate benefit to the children, the former plan seems more effective, its application being limited to those children who need it most; but it is to be hoped that for purposes of standardization some of us will concentrate our efforts, if need be on only a single station. This will possibly be at the expense of the present pre-school age generation, but will react to greater benefit on the many generations to come.

The Procedure Summarized

Briefly to summarize the foregoing statements: The procedure to be followed in the health supervision of older children differs from the established procedure for infants. This difference is mainly due to the increased importance of environment with the beginning of childhood; the need of the community, and especially of the mothers, for education; and the need of securing the children's cooperation.

The following subjects are those which now appear most worthy of discussion: (1) The maintenance of accessory clinics (posture, dental and nutrition). (2) The training of workers. (3) Frequency of physical examinations and reporting to conference. (4) Limit of registration for each station. (5) Methods by which the work may be extended.

PLEA FOR DEFECTIVES

In the ungraded schools of New York City alone there are about fifteen thousand children, the term "ungraded" being used to designate mental defectives, mental retardation on the part of foreign children, or children otherwise handicapped. More special classes are needed, especially for a large percentage of congenitally deaf children who speedily reach the normal standard under proper instruction. In the interest of normal children the Children's Council Committee urges in their report that no mentally defective child should be in classes for normal children, and if capable of being trained in the public schools, these cases should be in special classes or special schools for defectives.

There are constantly 1,000,000 cases of active tuberculosis, with an annual death rate of 150,000. Profiting by the great crusade for better care and nursing, this rate has fallen since 1904 from 200 per 1,000 population to 145. There are 1,100 tuberculosis associations now at work, 613 sanatoriums, day camps and hospitals. Specially trained nurses are badly needed to care for them, to help in treatment, prevention, and research.

VENEREAL DISEASES—EDUCATIONAL VS. SANITARY AND LEGAL MEASURES TO SUPPRESS

BY CARL SCHEFFEL, PH.B., M.D., BROOKLINE, MASS.

THE country having at last awakened to the prevalence of venereal diseases, sufficient enthusiasm has been aroused to give serious attention to this matter as a real public health problem. The United States Public Health Service and various other agencies are sitting up and taking notice, so to speak, of the serious advances upon our younger population venereal diseases have made, and measures are being sought to adequately combat this evil. In addition to the widespread establishment of venereal disease clinics as a curative measure, the greatest activity seems to be along educational lines. No sane person would question the great value of educational measures in diminishing these diseases, but the manner in which this education is distributed, and just who are most in need of it, are matters worthy of much consideration.

Too Few Are Reached

At present, the bulk of this educational activity seems to be directed towards the education in sex matters of young men and women in school and college. Sex physiology, sex hygiene, and sex continence are strongly dwelt upon in much of this literature. These are admittedly all of the greatest importance, and yet, they serve only that portion of Young America who have enjoyed a reasonable degree of education. Educational literature that would effectively reach the comparatively uneducated factory workers who represent millions of our young men and women, is much less abundantly distributed and far less explicit in its teachings. At the same time it is known that the prevalence of venereal diseases is greatest among the less educated, and that it is this class which most imperatively needs prophylactic instructions.

It being understood that some of the chief channels for the spread of these diseases are a certain type of dance hall and lodging-house, amusement resorts, for-hire automobiles, etc.; then it becomes desirable that a little more propaganda should be directed toward these places and to those who patronize them. In addition to directing a little more educational activity towards the "younger sporty element," if I may so designate it, a survey of police activities in so far as they concern the enforcement of our moral and sex codes and the disposition of the offenders of these codes by many of our courts, would indicate that there is urgent necessity of first educating the guardians and defenders of our laws before their intelligent support in the campaign to suppress venereal diseases and the causes that lead to them can be anticipated.

This brings us to the legal and sanitary aspect of the situation. The possibility and logic of attacking this

The scientific attitude presupposes the grouping of all the facts relevant to a situation and the formation of impersonal and unbiased judgment on the basis of carefully accumulated facts.

Conclusions reached in this manner bearing on health matters which have found expression in correlated action have resulted in the control of smallpox, in typhoid epidemics being regarded as disgraceful. Malaria and yellow fever are diseases which will soon be in the same category.

Results are not so immediate in disease prevention which requires individual instead of mass action. Laws generally are no more effectual than the people desire them to be, hence the necessity of educational measures to produce the efficient background of an enlightened public opinion in the matter of venereal diseases, which are most pressing public health problems.

problem from a sanitary and legal point of view seems to be scoffed at as impractical by many who are interested in the suppression of venereal diseases. The potency of normal sexual passion and the alleged interference with personal liberty seem to be the chief bugbears that make doubtful in the minds of some the feasibility of utilizing our legal and sanitary codes as effective measures in diminishing these diseases. It is true, no amount of education, sanitation, or legislation will suppress normal sexual passion—neither is such a result at all intended

or even desired; but, when the fear of interference with personal liberty is expressed in connection with this work, the history of all successful sanitary undertakings of note needs to be taken into consideration.

All modern public health measures, to a greater or lesser extent, affect the personal liberties of those they involve. Compulsory vaccination against smallpox was perhaps the first universal example of successfully combating by sanitary measures a serious and widespread disease. The wonderful results that compulsory vaccination has achieved in the diminution of smallpox need no further comment. Was the interference of so-called personal liberty so big a bugbear in this connection that it could not be overcome? Even today there are thousands of individuals in all walks of life who do not believe in vaccination and who raise a huge cry before our legislative bodies that they "do not want their children inoculated with poisonous germs in order to send them to public school"; yet for the safety of the nation we cannot submit to these antagonists. If vaccination against smallpox were made a voluntary rather than a compulsory measure, in another decade thousands of cases of this disease would be encountered where we now meet an isolated one.

The successful completion of the Panama Canal was made possible only through the practical eradication of yellow fever and malaria from this district. When it was learned that the mosquito is the carrier of these diseases, were half-hearted legal or sanitary measures applied to exterminate their cause? Or was the personal feeling or liberty of the individual inhabitant taken into consideration in enforcing the necessary measures required to eradicate these diseases? Not much. Health in the Canal Zone was realized because this difficult task was given one man with supreme power to perform. Fortunately this man had the gumption to express and carry out his convictions until he became complete master of the situation. If a mollicoddle attitude of considering the personal liberties of the population had been assumed, these diseases would never have been eradicated and there would be no canal today.

We keep police forces in our cities because there is

always a minority of our population who, if left uncontrolled, will endanger the majority; and in practically every public health problem there is always a minority that will not respond to educational or other rational voluntary means to comply with the sanitary measures to solve the problem. Concerning venereal diseases, it is a moot question whether it is the minority or the majority that will respond to voluntary measures intended to diminish these diseases. If for no other reason, this alone would indicate that only through compulsory measures can we effectively combat this scourge.

The opponents of compulsion in this task have raised the argument that public opinion is against the employment of stringent means in suppressing venereal diseases and the causes that allow them to flourish. The truth of this may be granted; but public sentiment to a certain extent even up to the present time has been opposed to the compulsory vaccination against smallpox, and is probably antagonistic towards other public health measures. Public opinion, however, can be directed, and is being influenced every day by the daily press for partisan and other purposes. Why not use the press for the worthy purpose of aiding in the suppression of venereal diseases instead of simply letting it be the means of referring to venery and its consequences in a sensational manner?

Why Fear Public Opinion

The country has been brought face to face with the cold fact that venereal diseases have become so serious a menace to the physical and moral well being of young Americans that our national efficiency is becoming endangered. Why not, then, look this menace squarely in the face and deal it the blow that it must get for the best interests of our country without taking into consideration the so-called personal liberties of that class of men and women who deem it their peculiar privilege to violate our moral and sex codes?

Laying aside all highbrow terms couched in prefixes and suffixes that lead the public to believe that the suppression of venereal diseases would involve the abridgment of personal liberty, is it not an absolute fact that the accepted moral and sex standards of our country do not condone sexual relationship outside of the matrimonial state, and that every state and territory in the Union has laws that make illicit intercourse a criminal offense? We know that far more than 90 per cent of all venereal diseases are acquired and spread through direct sexual contact, and that by far the greater majority of them are also acquired and spread through illicit sexual relationship. These are facts that nobody at all familiar with these problems can rationally deny. Where, then, does the fear of public opinion come in? Are we, as a great nation, to make laws and regulations governing our standards of moral and sex conduct and then deliberately fear the opinion of those who choose to break them? It would hardly seem that we have reached that stage of retrogression.

Who is it that rebels against the strict enforcement of our moral and sex codes that would lead to the direct suppression of venereal diseases; is it the clean living and law abiding citizen who has daughters of his own to protect, or is it the man and woman leading a life of double moral standards, or possibly financially profiting through the indirect sources that make the incurrence and spread of venereal diseases possible? The question requires no answer; nor do we need to fear the public opinion of this class of men and women, regardless of how numerous they are in any given community. They are, one and all, moral cowards, first because venereal diseases are—with the exception of the percentage that

is willfully transmitted to innocent and unsuspecting wives—acquired through dark and underhanded methods that will not survive the light of publicity; secondly, those who acquire and transmit them in this manner very well know that they are law breakers who endanger the public health and morals of the country. If we are really desirous of suppressing venereal diseases and their causes, public opinion or sentiment of those who spread these diseases are not to be feared; although they may be numerous, they have no moral or legal ground to stand on.

Educational measures are a very valuable means of aiding in the diminution of venereal diseases by laying a solid foundation for their prevention in the future, but strict enforcement of our sex and sanitary codes is the most important factor in suppressing these diseases where they at present flourish. The venereal problem has never been attacked in the same spirit or by the same methods as the eradication of smallpox, yellow fever, and malaria. For a long time we did not know the cause of the spread of these diseases and therefore could do nothing to prevent their transmission; but we do know the causes that make the incurrence of venereal diseases possible, we do know how they are spread, and we have already many well established laws on our statute books which, if they were properly and efficiently enforced, would greatly diminish the prevalence of these diseases. The segregation of prostitutes and other quasi legal and sanitary measures imported from foreign countries that have been tried out from time to time were futile and inconsistent. They proved entirely useless in the diminution of venereal diseases in the communities where they were tried out, because they deliberately encouraged the contraction of these diseases, and they were wholly inconsistent with American ideals and spirit because they directly condoned illicit sexual intercourse in flagrant violation of our laws which make this a criminal offense.

On the other hand, it is an absolute certainty that the strict enforcement of our moral and sex codes in any given community, together with adequate educational propaganda to arouse public sentiment, if carried out by one fearless, responsible head, would be an experiment resulting in great diminution of venereal diseases in that community in a surprisingly short period of time. During the war a somewhat similar experiment was tried in the vicinity of several large training camps, and proved quite successful as demonstrated by the low percentage of venereal diseases acquired by the soldiers of these camps. Then why not give the strict enforcement of our moral and sanitary codes a similar opportunity to produce equally splendid results among the civilian population in a given district? The task is by no means impractical or impossible if given an earnest trial and supported by Uncle Sam himself.

ASSIST MEDICAL SCHOOLS IN EUROPE

The Rockefeller Foundation announces a cooperative program to assist medical schools in central Europe by aiding in the rehabilitation of scientific equipment; by enabling universities to secure medical journals, and by promoting investigation of English and American medical schools, by representatives of Belgrade University as guests of the Foundation, this last feature being undertaken with the idea that Belgrade is one of the strategic points where a medical school must be established in the near future. Further assistance will be given by lending a technical adviser and by providing fellowships in special medical post-graduate study for persons who may be under appointment or consideration for the faculty for the proposed school in Belgrade.

CONFERENCE OF SOCIAL WORK

The next annual meeting of the National Conference of Social Work will be held in Milwaukee, Wis., from June 22 to 29, 1921. Subjects to be considered in the meetings of the Divisions on Health and on Mental Hygiene are as follows:

Health Section

Cooperation and Coordination in Health Work.

- (a) The National Council of Public Health—Organization and Program.
- (b) National Council for Coordinating Child Health Activities.
- (c) How Can Voluntary Organizations Best Cooperate with Health Officials?

The Health Program of the American Red Cross.

- (a) The Social Significance of Health Centers.
- (b) Cooperative Health Plan of the New York County Chapter.
- (c) Public Health Nursing Program and Activities of the A. R. C.

Social Significance of Child Health Work.

- (a) Education in Health Habits.
- (b) What State Bureaus of Child Hygiene are doing to Promote Child Health.

Government Agencies in Their Relation to Health.

- (a) The United States Public Health Service.
- (b) The Children's Bureau.
- (c) Department of Agriculture, Extension Service in Home Economics.
- (d) Bureau of Education.

Joint session with Division I.

- (a) The Undernourished Child—The Significance of Bringing him up to Standard.
- (b) Where Should This Nutrition Service Next Be Centered; in the School Room; in the Child's Own Family, in the Home?
- (c) How Much More may be Expected from Medical Service in the Public Schools?

Mental Hygiene Section

Mental Hygiene Problems of Normal Childhood and Youth.

- In Elementary Schools.
- In High Schools.
- In College.

Mental Hygiene Problems of Subnormal Children.

- In the Public Schools.
- In Institutions.
- In the Community.

Mental Hygiene Problems of Maladjusted Children.

- In a Public Clinic.
- In School.
- From the Teacher's Point of View.
- From the Physician's Point of View.
- In Institutions.

Educational Value to the Community of Mental Hygiene Agencies.

- The Psychopathic Hospital.
- Psychiatric Social Work.
- Mental Hygiene Clinics.
- Mobile Psychiatric Clinics.

The Basis of an Education.

- What Teachers Want to Know About Mental Hygiene.
- The Part Mental Hygiene Plays in the Solution of School Problems.

Speech Disorders in School Children.

It is anticipated that among those who will speak at these meetings will be: Dr. Donald B. Armstrong, Mr. Courtenay Dinwiddie, Mr. Sherman C. Kingsley, Mr. Philip Platt, J. Mace Andress, Dr. Ada E. Schweitzer, Dr. C. A. Pierce, Dr. Anna E. Rude, Dr. C. F. Langworthy, Willard S. Small, Dr. E. V. McCollum, Dr. Caroline Hedger, Esther Loring Richards, Dr. Frankwood E. Williams, Meta L. Anderson, Dr. William C. Sandy, Dr. Arnold L. Jacoby, Dr. Sanger Brown, Dr. Herman M. Adler, Dr. William F. Lorenz, Mary C. Jarrett, Dr. Douglas Singer, Dr. Stewart Paton, and Dr. William A. White.

The Conference will hold its meetings in the Auditorium, which is the most remarkable building of its kind in the United States. It has all the requirements necessary for the ideal convention hall, ample seating capacity, perfect appointments, accessibility and adaptability, abso-

lute safety, complete accessories in the shape of wardrobe, toilets, telegraph and telephone, storage accommodations with ample provision for exhibition space, banquet and assembly rooms, and committee rooms. It occupies an entire square just north of the main thoroughfare of the city and is readily accessible from all railway stations and interurban lines and forms the nucleus for the projected civic center of the city of Milwaukee.

The main auditorium is constructed without a single pillar or post to obstruct the view. It is located on the ground floor, and all parts of the hall may be reached from the street without ascending stairs. It has a flexible seating arrangement so that from five to ten thousand persons can be comfortably seated, and the acoustic properties are exceptionally good. All meetings of the Conference, both general and divisional, will be held in this one building. In addition to the great General Assembly Hall, there are four other large halls seating from 900 to 1,200 persons each. This will be the first time in the history of the National Conference that all the meetings could be held under one roof without crowding or inconvenience.

Milwaukee in June is an ideal convention city, located as it is on the shore of the lake, with ample parking and beach facilities. No section of the city is without a public park within ten blocks of it. Over 1,200 acres, all connected by a boulevard system, constitute the park system of this great city of the central west. In addition to its parks, the city has forty public playgrounds.

There are daily boat lines with large steamships from Chicago, and from cross lake ports. It is possible for visitors to come to Milwaukee by all lake line from Buffalo or by part way lake travel from Chicago, Detroit, Grand Haven and other ports. The Chicago North Shore Electric Road operates hourly trains from North Evanston.

Hotel accommodations are ample, as has been proven by the fact that Milwaukee has entertained so many large conventions in the past few years.

A large number of allied organizations will hold meetings in Milwaukee either immediately prior to or during the week of the National Conference meeting. Among these allied organizations will be: The Lutheran Inner-Mission Society, Social Service Department of the Protestant Episcopal Church, Public Health Nurses' Association, the National Urban League for Social Service Among Negroes, the Jewish Conference of Social Welfare, the Canadian Conference of Public Welfare, Foreign Community Workers, National Board of the Y. W. C. A., the National Association for Community Organization, the American Association of Hospital Social Workers, the National Federation of Day Nurseries, Interstate Conference on Education of Backward, Truant, and Delinquent Children, American Association for Organizing Family Social Work, National Children's Home Society, National Child Labor Committee, and National Travelers' Aid Society.

FAVILL MEDICAL LABORATORY

The medical friends of Henry Baird Favill of Chicago are raising a Foundation, the object of which is to establish the Henry Baird Favill Memorial Laboratory. Dr. Favill was a pioneer in the field of preventive medicine and his whole career was devoted to an effort to conquer disease by preventing it, and this for the double purpose of preventing possible disease and in conserving the essentials of community values by bringing life to a higher level for every individual. A laboratory such as outlined by the Foundation is considered to be a fitting expression of Dr. Favill's life work.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

HEALTH AGENCIES UNITE

A most important move in the direction of coordinating the health activities in the United States has been initiated as a result of a conference held in Washington, December 10, 1920, whereby the National Health Council has been organized and the following officers elected: Chairman, Dr. Livingston Farrand, chairman of the Central Committee of the American Red Cross; vice-chairman, Lee K. Frankel, of the American Public Health Association; recording secretary, Dr. C. St. Clair Drake, of the Council of State and Provincial Health Authorities. The election of treasurer was deferred until further consideration could be given to the whole question of financing the project.

The following list of activities has been approved as indicating the legitimate field in which the Council may function: (1) A special information bureau, (2) a legislative bureau, (3) the coordination of health activities, (4) periodic joint conferences, (5) a statistical bureau, (6) the development of educational health material. In accordance with the by-laws adopted by the Council, each member of the organization has appointed one representative and one alternate. The original members, with corresponding representatives and alternates, the representative being the person first named in each instance, are as follows:

American Public Health Association, Dr. Lee K. Frankel, Dr. M. P. Ravenel. American Red Cross, Dr. Livingston Farrand, Dr. E. A. Peterson. American Social Hygiene Association, Dr. William F. Snow, Mr. Baseom Johnson. Council of State and Provincial Health Authorities, Dr. C. St. Clair Drake, Dr. E. R. Kelley. Council on Health and Public Instruction of the American Medical Association, Dr. Watson Rankin, Dr. Frederick R. Green. National Child Health Council, Dr. Philip Van Ingen, Mr. Courtenay Dinwiddie. National Committee for Mental Hygiene, Dr. Thomas W. Salmon, Dr. George K. Kirby. National Organization for Public Health Nursing, Miss Edna L. Foley, Miss Mary S. Gardner. National Tuberculosis Association, Dr. Charles J. Hatfield, Dr. J. Alexander Miller.

The by-laws provide that "other national health organizations may hereafter be elected to membership by two-thirds vote of the members." Provision is also made for advisory or conferring, as well as directly participating, members. The International Health Board probably will, together with official agencies such as the United States Public Health Service, be associated with the Council in this capacity.

An official statement issued by the officials of the Council says: "The Public Health Council, representing as it does many prominent national health agencies, should

serve as a valuable clearing house and coordinating center, in many fields where common functions are performed. It aims to be an integrating force among independent autonomous agencies, rather than a merger of such agencies into one organization. It should increase the economy and effectiveness of operation, should eliminate duplication of effort, and should enhance opportunities for sympathetic and constructive public service. Such a movement, through its membership, and through a mutually helpful relationship with the state and local voluntary health agencies, should effectively serve the declared object of the National Health Council, which is: "the betterment of health work in the United States."

OKLAHOMA NURSES' INSTITUTE

A two day public health nurses' institute attended by about forty public health nurses from all parts of the state was held in Oklahoma City, February 18 and 19 under the direction of the Oklahoma Public Health Association. These gatherings are held three or four times each year for public health nurses employed by all organizations, and have been found eminently successful, not only in imparting much useful knowledge and information, but more especially by giving the nurses a broader outlook on the field of public health, encouraging those who are laboring in pioneer communities.

The institute consisted of lectures, round table discussions, and demonstrations. Following is an outline of the program: "Development of Public Health Work in Oklahoma," Jules Schevitz, general secretary, Oklahoma Public Health Association; "Coordination of Public Health Nursing in Oklahoma City," Miss Margaret Howard, superintendent, Oklahoma City Public Health Nursing Association; "Health Program Before the Eighth Legislature," Dr. A. R. Lewis, state health commissioner; "Consultant Tuberculosis Service," Dr. L. J. Moorman, president, Oklahoma City Anti-Tuberculosis Society; and "Health Crusade Tournament," Miss Henriette Hart, Crusader executive, Oklahoma Public Health Association.

A school nursing demonstration was held under the direction of Miss Anna Stanley, school nursing supervisor of the Southwestern Division American Red Cross, and the round-table was led by Miss Rosalind Mackay, state director of public health nurses. The meeting was featured by an inspection of the open air school and by an exhibition of health films, also a plea for recruiting of student nurses by Miss Ethel G. Pinder, director of division of nursing, Southwestern Division American Red Cross. Mrs. Bessie McColgin, the only woman member of the Oklahoma House of Representatives, delivered an excellent address on women's and children's legislation.

CHILD HYGIENE ACTIVITIES IN GEORGIA

BY DOROTHY BOCKER, M.D., DIRECTOR, DIVISION OF CHILD HYGIENE, GEORGIA STATE BOARD OF HEALTH,
ATLANTA, GA.

THE activities of the Division of Child Hygiene of the Georgia State Board of Health are similar to those of other divisions of child hygiene, although the particular method of carrying these out, the particular order of precedence and stress given the points are different. The Division has as its object: (1) proper prenatal care of the child, (2) proper postpartum care of the mother and child, (3) registration of the child's birth, (4) proper care of the infant and pre-school age child, and (5) a physical examination and follow-up work for every school child in Georgia. Some of these plans are being carried out, while others are still being organized. The Division is so new—having but six months' work to its credit—that some of the plans have not been initiated, that the work is not as broadly in effect as it will be in a year or two, and that some of the organization is still in its most rudimentary form. The child hygiene work will eventually be carried on by the county commissioners of health, who are full time health officers, but who number only twenty at the present time. The problem is at present, therefore, a two-fold one, (1) presenting the work to the county commissioners of health, and (2) the more difficult task of getting the work across in those counties that have no health organization. It is an interesting commentary, by the way, that commissioners of health are, as a whole, conversant with problems of water supply, sewage disposal, epidemic control, venereal disease, etc., but know very little or nothing about child hygiene or the organization of this work; and, what is a sadder reflection, the usual medical school has little in its curriculum to supply the need.

The first phase of the work—that of the prenatal care of the mother—will eventually be handled by the prenatal clinic. Very little, if any, prenatal work is being done, as yet, in Georgia; it is work most difficult to handle in southern communities. To force the issue before other phases of child hygiene have been accepted and established, or in places where other forms of public health work are still in the balance, would only result in failure. However, a start will be made within the next year.

The care of the mother during labor is receiving the following consideration: plans for educating the midwives and, after a year or two, the use of some form of certification, are under way, as also are plans whereby a suffi-

cient quantity of 1 per cent silver nitrate solution to last the general practitioner a year is to be supplied to the physicians and midwives at a cost of 21 cents; this will make compliance with the "Act for the Prevention of Blindness" easy.

A pamphlet on Birth Registration has been sent to some five hundred organizations and publications; this gives a brief résumé of the history of birth registration, reasons for birth registration, etc., and finishes with the following: "There is a registrar in your registration district.

If you do not already know him, find out who he is. See that all concerned do their full duty with reference to birth registration." Georgia is not yet in the birth registration area, but it is hoped by such measures that she will be shortly. In addition, each physician has been supplied with as many form postal cards as he can use; the postals require him to fill in all the facts with reference to the newborn child, in return for which the mother has sent to her the Baby Book; the returned cards are then turned over to the Bureau of Vital Statistics and there records are checked up.

The Georgia Baby Book has been distributed throughout Georgia by the physicians, nurses, mothers' clubs, and other interested agencies. In addition, for the infant group, there are diet slips,

similar to those included in the Baby Book, that the mother can pin to the kitchen wall; these are for the bottle-fed baby, directions to the mother of the breast-fed baby, diet for the twelve to eighteen month old child, for eighteen to twenty-four month old child, for two to three year old child, and for the three to six year old child.

The Children's Health Centers are extremely valuable aids; usually in the rural districts the commissioner of health meets the infant and pre-school children every other week or only once a month in winter, but more frequently in the summer. In the town the center is open once a week; in the cities there are usually enough applicants to justify opening for several days. These centers are initiated and organized by the county commissioners of health, the women's clubs, the Parent-Teacher Associations, nurses, etc., receiving aid, especially along the lines of propaganda and finances where needed, from the Rotary Club, the Chamber of Commerce, etc., the various physicians of the community contributing their professional services. In places where a pediatrician is em-

Proper follow-up makes the work effective.

Home the next morning, cheerful and happy.

ployed, a small fee is charged for the visit or for the year, either for the individual child or for the children of the family. It is distinctly understood that the children's health centers are not primarily for indigent children, but for children of the rich as well. There are some twenty children's health centers in actual running order; we hope to triple this number by summer, so as to have an effective weapon against the terrific summer

child mortality of Georgia, (last July 58 per cent of all deaths were of children under ten years of age). On the first visit to the center the child is given a physical examination; subsequently the child's weight is taken, and a conference with the mother as to the child's food and feeding, habits, his clothing, his hours of sleep, etc., is held and definite advice along hygienic lines is given, or, if need be, the mother is referred to her family physician or a specialist. In a few places, the poorer children are given this aid in clinics connected with the children's health centers. Literature is distributed and lectures and lantern talks on pertinent subjects are given by trained persons.

The school work gives the biggest results, since large masses of children can be handled in comparatively little time. The school is not only a good machine—no further organization being needed for the building of such a machine—but also it has back of it a powerful tradition. Physical examination, of both white and colored children, is required by law in the counties having health officers. The examinations in the rest of the state are done by this department directly, but only in places where there is assurance that there will be effective follow-up work, and by local agencies in a few places in a very spasmodic way. To examine a great many children in a limited time, a larger personnel is needed for next year. Eighteen thousand children have had a physical examination in the last six months. The method has not been entirely uniform up to the present, but we are advocating the use of our physical examination blank. As can be seen, this covers all the essential points, requires the minimum amount of bookkeeping, requires follow-up work, is easy to file and to handle, and eliminates the elaborate histories which are called for on so many of the cards and which take the time that belongs to the follow-up work and that exhausts the time and patience of those helping. The history needed to interpret a particular case is easily obtained and recorded under "Remarks." The blank also calls on the teacher for a share in the work. The exam-

iner explains, at a teachers' meeting, how to do this work and receives as a result not only valuable aid, but the finest kind of cooperation in all of the examination.

Special Clinics Organized

The follow-up card is sent by the teacher and filled out from the physical examination as made by the physician. In addition to the follow-up work there have been established a number of school clinics—in a few instances called children's clinics—that take care of the throat and nose work, the eye and the dental work. Nutrition classes have been organized in a great many sections. These groups are in every case classes and not clinics, although sometimes erroneously called clinics. Portable clinics for the rural sections are under advisement, since Georgia is essentially rural and touched to only a slight extent by the town clinics.

Literature is as follows: (1) Birth Registration, (2) Georgia Baby Book, (3) Diet Slips, (4) Children's Health Centers, (5) School Physical Examination Blank, (6) Follow-up Card, (7) Physical Examination of the School Child, (8) Nutrition of the School Child, (9) Nutrition Score Card, (10) The School Clinic. We have a panel exhibit consisting in all of seventy-three panels; also 157 lantern slides. The Division of Child Hygiene, in addition, has collaborated, in the preparation of the Manual of Physical Education, with the State Department of Education.

In addition to the above we have had occasion to send out and recommend selected pieces of the literature pre-

CHART II.—INCIDENCE OF SOME HEALTH DEFECTS. BASED UPON PHYSICAL EXAMINATION OF 10,000 GEORGIA SCHOOL CHILDREN (WHITE) FROM EVERY TYPE OF SCHOOL AND FROM EVERY SECTION OF THE STATE. EXAMINATIONS MADE AND GRAPH DRAWN BY D. BOKER.

pared by the American Medical Association, the Bureau of Education, Washington, D. C., the Child Health Organization, the Association for the Improvement of the Condition of the Poor, the Metropolitan Life Insurance Company, and the Department of Labor, Washington, D. C.

The field work done directly by the Division has been: conferences, lectures, lantern talks, organization of committees and school clinics, and has concerned itself with the commissioners of health, College of Agriculture (series of conferences and lectures on nutrition), women's clubs, parent-teacher associations, fair workers, teachers' institutes, local physicians, Red Cross nurses, anti-tuberculosis workers, chambers of commerce, Rotary clubs, etc.

The division feels that it has made a very effective beginning, but still, only a beginning, in the field of child hygiene in Georgia.

TYPHUS MEASURES IN SCHOOLS

As a part of the recent activities in preventive measures against typhus fever in New York, the inspectors of school children will undertake to care for the children who are infested with vermin.

POPULATION AN ECONOMIC INDEX

THE noblest and most difficult art of all is the rearing of human thoroughbreds, said Dr. Edward J. Kempf¹ in addressing the International Conference of Women Physicians in 1920. The crux of the whole matter is contained in the inheritance, vigor, and nurture that we give our children. Whatever the immediate motive of commiseration, conservation, or uplift that urges welfare work and promotes agencies for the more or less scientific supervision of mothers and their young children, the organized effort to protect the infant and to insure the welfare of the mother is an admission that the natural growth of population has not been maintained. The lowered birthrate which has undoubtedly been one of the factors leading to recent activities to secure the preservation has not been confined to one people, but has occurred in most civilized countries. Recent analysis has been made by Ballantyne² of a study made in England, Scotland, Wales, and Ireland, concerning itself with the extreme and persistent fall of the legitimate birth rate in the United Kingdom; the influence of antenatal disease and death in the decline of the birth rate; the contemporary movements of population and the proportional distribution of the sexes; the economic problems of parenthood; the housing situation in its bearings on parenthood; venereal disease as the chief cause of sterility and degeneracy; the increased industrial employment of women of child-bearing age; and the differential and qualitative aspects of the present birth rate. Appraisal is made of the constitution and uses of the Ministry of Health as an instrument of racial reconstruction, and the recommendations of the Commission include a census to be taken immediately after the war, together with the establishment of a permanent anthropometric department in the Ministry of Health.

Voluntary restriction of the birth rate is considered as one of the most important causes of the lowered birth rate. This phase of the subject is discussed pro and con from ethical, medical, and economic viewpoints, with the general conclusion it is the plain duty of society to remove the disabilities which, without any fault of the individuals concerned, may be imposed upon worthy parenthood.

They place great emphasis upon fertility in the different strata in the population. "The differential fertility of the least prosperous and successful classes is seen to be a new feature . . . of the birth rate situation, and we can no longer argue that it has probably been proved by experience to be compatible with rational advancement and prosperity." State aid of some kind is argued for the endowment of motherhood or of parenthood. The

whole report is a document of immense importance. The matters considered have ethical and religious as well as medical and obstetrical aspects and, while the Commission came to no close agreement, the third section of the Report is wholly constructive and seeks to retrieve the great losses to population because of deaths before and immediately after birth. The amelioration of antenatal, intranatal, and neonatal deaths is rightly regarded as in the sphere of the maternal section of Mother and Child Welfare. The influence of syphilis and alcohol as "racial poisons" is not forgotten.

Another angle of this important subject is given by Glaister³ in discussing Malthus and the Poor Law. Malthus laid down the following principles regarding the growth of population: (1) Population has a constant tendency to increase beyond the means of subsistence. (2) Population, when unchecked, has the power to double itself every twenty-five years under the most favorable circumstances; and (3) that means of subsistence increased by

arithmetical ratio, while the population increased by geometrical ratio. His object was to show that: (a) population is necessarily limited by the means of subsistence; (b) that population increases where these means of subsistence increase, unless prevented by powerful and obvious checks; and (c) that these checks and those which repress the superior power of population were resolvable into: (1) vice, (2) misery, and (3) moral restraint; further (4) that it was the duty of the statesman to discourage and diminish the former and to encourage the latter.

Kadel & Herbert.

A society milk station where the children come daily for the milk supplied as a necessary addition to insufficient diets.

On its economic bearings, Malthus said, "Hard as it may appear in individual instances, dependent poverty ought to be held disgraceful," and he held that society and the government which presides over it are without any direct power to remedy it. As to disease, he said: "Diseases have been generally considered as the inevitable inflictions of Providence; but perhaps a great part of them may more justly be considered as indications that we have offended against some of the laws of Nature. . . . The human constitution cannot support such a state of filth and torpor; and as dirt, squalid poverty, and indolence are in the highest degree unfavorable to happiness and virtue, it seems a benevolent dispensation that such a state should, by the laws of Nature, produce disease and death as a beacon to others to avoid splitting on the same rock. In the history of every epidemic it has almost invariably been observed that the lower classes of people, whose food was poor and insufficient, and who lived crowded together in small and dirty houses, were the principal victims."

Wholly illuminative on the side of remedial measures and constructive in its tendency is the discussion of Sir Arthur Newsholme' before the Philadelphia Pediatric Society of Philadelphia in 1920. He considers the birth rate in its relation to infant mortality and analyzes in-

fant mortality as part of the general mortality of all ages. The primary objects of preventive medicine, he says, are to transfer as many deaths as possible from the earlier to the later periods of life, to prevent the larger mass of non-fatal illness which, from the point of view of the community, is even more serious than early deaths, and to raise the general standard of health of the population.

At least one-tenth of the total deaths at all ages occur in infancy. The most fertile field for preventive work is in the neonatal period. The discussion outlines what is being done by health authorities and what it is desirable to do generally in order to enable every mother to have the best care which modern medicine renders available. The care of the mother and the newborn infant should not be separated from general medical care on the one hand, or from general public health administration on the

Social preventive pediatrics devotes itself to helping the child in health by recognition and care of minor defects or ailments while they are still amenable to treatment.

other. Prenatal clinics should connect with postnatal clinics, the provision of maternity homes and hospitals, and periodical supervision of the mother and her children. At every point the physician will be needed, and departments of public health work must be called in aid.

S. P. M.

RELIEVE NURSING SITUATION

The great shortage of nurses that has been threatening the hospitals of New York City is being met in a unique way by women who in ordinary life belong to the leisure class. Two hundred volunteers have been organized by the New York County Chapter of the Red Cross, and placed on duty in fifteen of the largest hospitals.

By taking over such tasks as washing patients, wheeling them to and from the operating room, making beds, checking laundry, and taking the histories of patients, they are releasing scores of nurses for more difficult duties. A large number of women who took Red Cross courses in home nursing during the war are acting as nurses' aides, doing practically everything the nurse does in the wards except give medicine.

Red Cross workers have also taken over the making of surgical supplies and hospital garments in a number of the hospitals. Though they receive no pay for what they are doing, many of them give full time. Others give two or more afternoons each week. New volunteers are coming in at the rate of fifty a month.

Once insure that the air in a house is stagnant, and sickness is sure to follow.—Florence Nightingale.

Kadel & Herbert.

The welfare of the mother lies largely in her own hands, provided that economic conditions favor her care, and that she is properly instructed when help is required.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

HOOKWORM INFECTION IN THE ARMY

RESULTS of an interesting investigation into one of the war medical problems appear in the first issue of the recently published *American Journal of Hygiene*, dealing with the relationship of infection by hookworm to the incidence of morbidity and mortality in the army. Of 22,842 men examined at a certain camp, 3,014, or 13.5 per cent, were found to be infected with hookworm though the greater part of the infections were light and without clinical symptoms. The purpose of the study was to determine the increased burden of morbidity and mortality due to the presence of hookworm infection. Does hookworm infection influence the severity of infectious disease; does it increase a susceptibility to disease; and what influence has it on army efficiency?

The extent of morbidity can be measured by the number of sick calls and the number of hospital admissions per man during a given period. Quoting from the report,¹ "Among the 13.5 per cent positives there was an increase of 27.9 per cent in men sick. Hospital admissions are 76.5 per cent higher in positives. . . . and sick calls show 86.6 per cent increase among hookworm hosts." While the increase of men sick is 27.9 per cent, the increase in hospital admissions is 76.5 per cent, indicating an increase in severity of disease among positive hookworm cases, as compared with so-called negatives. Ten organizations having more than 10 per cent hookworm infection had a mortality rate of 1.5 per cent, or 87 per cent above that of seven others with lighter infection, whose average was 0.8 per cent. As concluded by the authors of the study, "Sickness, whether mild or severe, acute or chronic, is increased among the men who are weakened in general health by hookworm infection."

The available data do not show that hookworm is responsible for an increased susceptibility to particular diseases, though a small percentage of increased incidence of tonsillitis, laryngitis, measles, bronchitis and pneumonia is noted among the positive cases. The incidence of tuberculosis is decreased, but this is probably due to the elimination by draft boards of men giving clinical evidence of hookworm plus active pulmonary tuberculosis. A striking fact is the increased mortality from pneumonia among the positive cases. For example, a 284 per cent increase in a certain regiment in the rate of infection by hookworm above that of the rest of the division was accom-

panied by a 325 per cent increase in the mortality from pneumonia in that regiment.

Intellectual inferiority is frequently associated with hookworm infection, though such inferiority is doubtless the result of a vicious circle of factors, of which hookworm is but one. From the standpoint of economy and efficiency, it is the opinion of the authors that the elimination of hookworm infection as a soldier enters the service would be more profitable than to allow him to continue untreated.

ETIOLOGY OF YELLOW FEVER

NOTABLE among recent scientific accomplishments is the isolation of *Leptospira icteroides* by Noguchi¹ of the Rockefeller Institute, and its designation as the specific pathogenic agent in the etiology of yellow fever. With his characteristic sound bacteriological procedure, Noguchi has cultivated this organism from yellow fever cases in Guayaquil, Merida, and Peru. The properties of *Leptospira icteroides* agree with the well known properties of the yellow fever virus and, when carried by the *Stegomyia* mosquito and transmitted to another host, can reproduce the disease. Agglutination and other immunity reactions of the organism also indicate its specificity in the causation of yellow fever.

Epidemic yellow fever is on the wane, though the disease appears in endemic form in Yucatan in Mexico, Guayaquil in Ecuador, in the Amazon river region, and on the west coast of Africa.² The chances for an epidemic of yellow fever in this country are extremely remote, principally because our seaport cities do not furnish *Stegomyia* females necessary for transmitting the disease from one patient to another. A vigorous anti-*Stegomyia* campaign such as was waged by Gorgas in Panama can prevent the spread of the disease and ultimately bring about its control, since the virus exists in the patient's blood only a few days. Yet there is always danger of the introduction of new infectious material, and if the sanitary measures have been lifted or slackened, a recurrence of the disease is possible. The campaigns waged so successfully in Havana and Panama can be imitated in any community with modern public health machinery, though far more difficult of accomplishment in thinly populated regions with undeveloped sanitary organization.

Without the knowledge of the causal organism, no at-

tack on the seed-bed of the disease is possible. Noguchi was able to isolate the organism from the virus in the patient's blood as late as the sixth day after the onset of symptoms, whereas our prophylactic measures have assumed the virus not to exist beyond the third or fourth day. This discovery will influence the sanitary regulations for the control of the disease and the precautions

observed during the infective period will have to be prolonged.

With the isolation of *Leptospira icteroides*, efforts can be directed to the preparation of a serum for purposes of treatment and prevention. Such studies are already under way and final victory over this deadly enemy of mankind is in sight.

PEACE POLICIES IN REVIEW

By MARION L. STEIN AND BLANCHE W. THATCHER, PHILADELPHIA, PA.

IT WAS for the purpose of an efficient coordination of general health activities that at the close of the war the Federal Public Health Service asked the assistance of the American Red Cross in planning a program of preventive and educational work. As this was of such wide scope, it would of necessity include the reconstruction of the ex-service man and his family. This governmental department followed the same course it had always taken, namely, that of stimulating the state work along these lines. But it soon came to a realization of the fact that to be progressive it must profit by experience such as inevitably falls to the share of an organization like the Red Cross during a war emergency. When we consider the ravages made by four years of war, famine, disease, and disaster in Europe, and the consequent reaction in the United States, incidental to immigration from there, the task may well be considered as illimitable. This was early recognized by men of the most scientific intellects. The result was the world movement for the conservation of health, organized at the Geneva Council by the League of International Red Cross Societies. A program was devised that saw not only the control of disease and epidemics, but the significance of focusing the attention of the nations upon posterity. It carried a special message to Youth.

In these days, so near the havoc wrought by war, no problem of child life could be considered without dealing with the offspring of those most closely affected by that war. Most of the young men enlisted in the service of the nation were of marriageable age, either having already assumed or being about to assume parental responsibility. Their children were brought into the world during a period of anxiety and emotional stress when many of these men were disabled and their vitality at its lowest ebb. Is it not therefore reasonable to feel that this work is not a specialized task for the government alone, but rather the individual responsibility of every member of the community? All available sources must be utilized—federal, state, municipal, public health work, and education.

Aftermath vs. After Care

It was the privilege of the American Red Cross representative placed by the Home Service Section of the Southeastern Pennsylvania Chapter in the District Supervisors Office of the United States Public Health Service for the medical care of the soldier to interview most of the young men applying to the government for physical examination and compensation during the first year of the reconstruction period. The tide of popular sentiment was still at high water mark. The misdirected but kindly efforts of the unskilled were so much in evidence that the so-called "hard boiled" methods were considered the only antidote by federal agencies. Frequently as much damage was done in the one direction as in the other. The

martial severity that discouraged any unspartanlike attitude on the part of the overseas soldier left its mark and made its reappearance on home soil. These men made a very earnest effort to rehabilitate themselves without government aid. It was often found difficult by Red Cross workers outlining war risk rights to persuade them to apply for their just dues. This is not said in disparagement of the home army, but rather in explanation of the attitude of the overseas army. The constant association with the Allied troops could not fail to make our men emulate the stoicism with which they met the continuous hardships, the trench-life monotony, the numerous deaths, and the appalling gloom of a nation in mourning. To them "disability" was synonymous with "failure"!

The first year of the reconstruction period was largely influenced by the Washington policy of urging the men to file their claims promptly, assigning a time limit of one year for eligibility. It is to be regretted, though probably condoned, that the emergent character of this phase of the work obscured the vital issue. It laid the emphasis on remuneration for services rendered and failed properly to provide adequate means for restoration by highly standardized methods of medical diagnosis and treatment. During the second year of the reconstruction period the hastily organized machinery has been considerably improved. At present the government has made provision in all United States Public Health Service Hospitals for sufficient medical personnel and occupational therapeutics. Medical and psychiatric social workers have been placed there by the Red Cross. There is still, however, a dearth of the latter, particularly in the psychiatric group.

This simplifies the problem of the man who is willing to accept hospitalization, but it does not make less complex the situation so far as the ambulatory cases are concerned. By "ambulatory" is meant those men whose physical condition was such as to make regular work impossible, but whose handicaps were not the kind to warrant retaining under the government. These needed continuous "follow up" home care and hygiene, not yet adequately provided. In fact, one of the disadvantages of medical service in its relation to state and federal health insurance has always been its failure to take an active and aggressive part in campaigns against disease and their prevention. Here indeed is an opportunity for the public health nurse and the psychiatric and medical social worker in the clinic to refute this criticism and to prove the plan socially constructive.

Year's Service Reviewed

We get a small idea of the volume and character of the service given to the men applying to the District Supervisor's Office of the United States Public Health Service by reviewing the method of procedure thought out with the utmost consideration by the Home Service Section

of the Home Service received notarial service, assistance in filling out the form of application according to the proper government regulations, and instructions in securing additional medical evidence. From there to the District Supervisor's Office was but a step. Here the Red Cross representative personally interviewed the men, often acting as intermediary between applicant and physician, frequently bringing to the attention of the latter significant social facts to illuminate an otherwise obscure problem and securing at first hand recommendations from the physicians. Later a visit to the home was promptly made by a Home Service worker and assistance and guidance proffered. The following is a short outline of the type and number of disabled brought to the notice of the Red Cross representative from September, 1919 to September, 1920. This gives a fairly accurate index of the relative incidence of the disabilities encountered, but does not serve to indicate the highly diversified services entailed.

Disabilities Encountered

Number	Number
Muscular atrophy 2	Paralysis (partial and total)..... 31
Amputations 49	Arms, limbs, fingers, etc., result of war injuries 118
Double amputations.. 3	Pes planus (double)..... 21
Arthritis 53	Pleuritic adhesions..... 138
Bronchitis, Gas, Asthma and Emphysema.... 465	Rheumatism 11
Burns (gas)..... 6	Sacro-iliac disease..... 9
Carcinoma 7	Scolioses 10
Cardiac cases..... 293	Arteriosclerosis 1
Dental conditions..... 138	Multiple sclerosis..... 28
Ear, nose and throat operations 316	Skin diseases..... 28
Empyema 12	Surgical wounds and operations
Lethargic encephalitis.. 1	Nerve injuries, impairment of function 624
Epilepsy	Synovitis, chronic..... 7
True 32	Syphilis and gonorrhea..... 135
Traumatic 3	Neuro-syphilis 2
With mental complications 3	Tuberculosis
Eye injuries 374	Bone 2
Fractures 89	Laryngeal 2
Gastritis 65	Peritoneum 2
Goiter, thyroid disturbance 8	Pulmonary 470
Hernia 80	Trench feet..... 3
Post-influenzal conditions 9	Tumors 6
Malaria 4	Varicose veins..... 16
Malingers 27	Final diagnosis unknown 281
Meningitis 3	Total 4,534
Mental and nervous..... 391	
Miscellaneous 185	
Palsy 2	

Form of Service Given

Number
Occupational guidance 335
Compensation adjustments—affidavits, insurance ratings 627
Diet and hygiene..... 71
Financial aid—home investigation, temporary relief..... 1,103
Outfitting patients for hospitals and sanatoriums.... 842
Contacts made between patients and doctors—compensation claims filed (new cases)..... 4,300
Orthopedic shoes secured..... 145
Removal of mental patients from prisons to government hospitals 6
Total 7,429

These figures do not include every service man known to the United States Public Health Service, but only those for whom the Home Service acted as intermediary between the government doctors and the patients during that particular period. It does, however, represent those of the Army and Red Cross Nursing Corps, many of whom applied for their War Risk rights and medical treatment through the Home Service.

It might also be noted that but twenty-seven of the

four thousand men applying for compensation could be termed malingers—a remarkably low percentage, and an obvious testimony to the inherent honesty of the American people. Again, it might be observed that on the whole venereal disease showed a rather low percentage. This is due in part to the splendid army instruction and discipline; for the greater majority were not discharged from the army until such a condition, if evident, had been arrested. The "Mental and Nervous" classification includes all varieties of psychoses induced by the war.

Orthopedic Measures

In various cases of trench feet, callosities, and general foot deformities attendant upon long hikes and exposure, the government doctors prescribed certain modified types of shoe. The Bureau did not make provision for shoes, but did cover the cost of orthopedic corrections. The man was expected to furnish his own shoes, but often he was unable to do so. Therefore arrangements for furnishing these so that treatment might be uninterrupted were made through the Red Cross representative.

In addition it might be permissible to state that an enormous percentage of applications were based on gas disabilities. For the very definite purpose of tying them up more closely to the federal agencies, the Home Service Section made a study of them and found that of the 1,050 men under care in May, 1920, ten had refused Public Health Service treatment, 616 had received no compensation whatever, 102 were actually in training with the Federal Board, and the others were pending adjustments of their government claims. The great majority were working very irregularly or at unsuitable occupations. All stated that they were in very poor health. They were brought to the attention of the Public Health Service early in the summer and the greater part received the special attention of the physicians in the Chest and Neuro-Psychiatric Examining Sections within the next three months. The result was that some were hospitalized, others specially recommended for training, and still others re-rated for increased compensation. Since then the Bureau of War Risk Insurance has become "ruefully aware" of the disastrous effects wrought by asphyxiating gases of modern warfare.

Indeed a panoramic effect of the whole picture may be obtained by an intensive glance at one special department of the Home Service Section. This was aptly termed the Casual Department. Serving as it did a transient population, every type of service man drifted through it from the wandering tramp returned with the added glamour of army life abroad to the better educated man whose career was interrupted at a period most likely to instil a restless wanderlust. Here, too, were found the mentally irresponsible, the ill adjusted lads at odds with families or relatives—in fact, all those held in the throes of an urge created mainly by a fleeting moment of larger opportunity. Have we, we wonder, lost sight of the importance of utilizing the dynamic force of an urge as potent as this?

Types of War Risk Problems

Because a few concrete instances are often more illuminating than many abstract examples it might be well to present three different types of problems brought to a satisfactory conclusion through Red Cross channels.

First, there was Russel X., who had tuberculosis in its most advanced form when he first applied to the Home Service. He was at once referred to the Public Health Service and hospitalized, but died soon after. To reinstate his insurance was impossible unless he could prove

his condition before death was the same at the time of his application as at his discharge. Several times his claim was refused; but finally, through the efforts of a Red Cross worker in cooperation with a local Bureau representative, the soldier's "case" was proved. On October 14 he applied for compensation and reinstatement of insurance; on November 7, his first compensation check was received; on November 11, he died; and on December 3, the government "came through" with a decision of permanent and total disability, making his insurance payable from the date of his discharge.

Second, and this instance is more unusual than typical, there was a Mrs. Y., the mother of a soldier who had suffered from tuberculosis before he was drafted, but who had always been her main support. From the time of his discharge until his death some two months later he was confined to his bed. He had not taken out insurance while in service. Almost two years after his decease his mother first applied to the Red Cross for compensation for dependency. Her claim was disallowed until sufficient medical evidence proved that the boy might have lived perhaps for years if he had not suffered from exposure in the service. Then, not only her compensation of \$20 a month was secured for her, but an additional stipend through the automatic insurance obtained at the suggestion and through the efforts of the Home Service worker.

The third type is represented by the case of Frank Z., a man who was fortunate in securing a complete and uninterrupted rehabilitation at a time when a break in the link of his restoration to health and earning capacity would have made of him a dependent neurasthenic. He was a gassed patient and immediately recognized as such by the public health doctors. He had been a fur dyer by

occupation. The physicians advised him not to attempt to continue this injurious trade process, remunerative though it was.

They arranged for hydrotherapy treatments, physical exercises, and proper medication. Very light work was advised and two positions were secured; the first, some sort of light electrical work, was too arduous; the second, a "checker up" of employees, was an outdoor job and a satisfactory "filler in" until agricultural training under the Federal Board was provided about three months later.

The Unfinished Work

It has been roughly estimated that in Philadelphia alone there are about twenty-seven thousand disabled men, whereas in Pennsylvania and Delaware, the two states coming within the jurisdiction of this Division of the Red Cross, there are in the vicinity of 35,000. In the light of past experiences with sickness in general, these figures assume a gigantic aspect. Add to them the large proportion of men found physically and mentally unfit for military service and the situation becomes alarming. Granted, much has already been done,—is being done; much more remains to do before that goal of health can be reached whereby the past can be obscured, the present reconstructed, and the future protected. Europe's many millions, dead of war, famine, and disease, cry out a veritable challenge for better things to America's countless numbers of living and yet unborn. That challenge can be adequately answered only when all men and women—individually—collectively—consecrate themselves, in the spirit of Lincoln's immortal words, to the task of realizing that "it is rather for us the living to be dedicated to the unfinished work,"

THE GRINNELL CLINIC

BY E. S. EVANS, M.D., GRINNELL, IOWA

THE Grinnell Clinic is an association of six physicians who originally came together for the purpose of furnishing support and financial backing for the Grinnell Community Hospital, built two years ago by public subscription. These men originally agreed to contribute the fees derived from hospital cases to a fund which should be used to guarantee the hospital against a deficit at the end of any fiscal year. This fund was allowed to accumulate until it reached a certain sum, after which all moneys put into it were to be divided equally among the men of the group. Because of their peculiar interest in the hospital, the trustees appointed these men as the staff of the hospital, and left to them the formulation of the house rules and general policies of the hospital and the training school.

Close association of this nature for the period of one year led logically to the acceptance of the idea of complete cooperation both inside and outside of the hospital, with the result that a clinic group was formed.

Group Practice Instituted

This group is an equal partnership. It is predicated upon the idea that efficiency in medicine, like efficiency anywhere, requires a rather complete degree of specialization. Each physician has a field of work assigned to him, in which he has the last word and in which he is expected to perfect himself as speedily as may be possible. Each man has agreed to drop as rapidly and completely

as he can the slipshod habits of practice which are the customary and familiar earmarks of many a country doctor, and to make full and careful histories and examinations, and to use the facilities of the laboratory to the fullest extent. All patients who can be persuaded to do so are encouraged to submit to careful clinical investigation, and this implies the clinical study of such cases by at least four of the six men constituting the group. A laboratory is in the suite in which the offices are located, which, in connection with the hospital laboratory, affords facilities for practically all of the customary laboratory investigations—bacteriological, serological, and pathological examinations, blood chemistry, urinalysis, analysis of stool, gastric contents, and blood work. The x-ray apparatus at the hospital is available for necessary radiographic work. The hospital laboratory is a branch of the State Board of Health Laboratory.

A system of case record is in use which reduces to a minimum the temptation to slight that side of the work, and the records of most patients—excepting ambulatory cases of minor medicine, etc.—are intended to be as complete as the case records and histories of hospital patients.

The Grinnell Clinic is attempting to conduct the professional part of their affairs in a manner which approximates as nearly as may be the minimum standard set for hospitals by the American College of Surgeons. Careful and complete histories are kept; adequate laboratory facilities are available; no case is operated on until a

history is written, the laboratory reports are in, and a consultation held; and very frequently before the procedure is determined upon the case is discussed in the daily conference. Pathological reports are made on all tissue removed at operation, and a follow-up system is being inaugurated.

Every day the members of the clinic hold a conference which lasts half an hour, at which various cases are discussed, usually a case that has been examined by a number of the men the previous afternoon. Occasionally some hospital case or some case which is on the call list out in town or country is discussed and recommendations made for the care and disposition.

Once a week two hours are spent, usually in the evening, at a meeting which is in the nature of a formal symposium on some particular subject of professional interest. The papers given at these meetings are intended to be careful digests of particular phases of the topic which has been assigned to the several men.

The financial side of the clinic was turned over completely to a business woman of considerable experience and tact. She sees that the books are properly kept and that collections are duly made and bills paid.

It has been found that the problems to be solved by a group of this kind, in an environment such as surrounds this group, are those which result from the conflict of the habits and customs of the general practitioner of the past (and present) with the effort to do careful scientific work. It has also been assured that the success of the business side of the group is the factor that ultimately determines whether or not the group can survive as a group. Moderate charges and collections carefully attended to, with a free list which is supervised by the local Social Service League, constitute the financial policy.

Apart from these considerations it has been found that, while most people appreciate the opportunity to have their difficulties carefully and completely investigated, there is still a sprinkling of those who admire and love to patronize the doctor who "can tell what is the matter just by looking at me." Occasionally someone complains that "Doctor So and So has doctored me for a long time and never had to examine me or make me take off my shirt." Then, too, there is some tendency on the part of such patients to suspect that this is a scheme for getting people into the office and passing them along from one doctor to another for the purpose of collecting a multiplicity of fees. Fortunately, these ideas are dying out quite rapidly, though tact was necessary in the beginning to combat them. Other doctors, too, have been more or less skeptical of the proposition and have pointed out, with some truth, that the doctors in the clinic have lived here all their lives, that they have never yet set the world on fire, and that it would probably not be noticed to be in conflagration yet for quite a while in this territory. These allegations have rather a firm foundation in fact. Doctors initiating such a plan in their own community do labor under a handicap from the general familiarity that grows out of long association. Some of this particular group were reared in Grinnell or in the vicinity, having practised here for varying lengths of time. None of them have become wealthy in the pursuit of medicine, though all have enjoyed good general practice. But they are men who see the handwriting on the wall. Their community demands more efficient service in other respects, such as lighting, heating, sewage disposal, waterworks, etc., than was available thirty years ago; and it is just as true that the community demands more modern and scientific care of its sick and disabled than it did thirty years ago. The old order passes. Many people of the older

generation are a little slow in seeing it, but a new day has dawned in the practice of medicine, and the Grinnell Clinic is endeavoring to bring to this community some of the benefits of recent advances in the medical sciences.

Organization Questions

From the doctor's point of view, a clinic must be run either by some man who is the arbiter and court of last resort, who takes all the profits and stands all the losses, paying the others a salary; or it must be an equal partnership. Clinics essaying to run on the pro rata basis inevitably break up. The men forming the Grinnell Clinic are equal partners, and it is their unanimous opinion that the personal satisfaction in this association and the great joy in the cooperative labor at hand more than compensates for any seeming inequality in the way of prestige sacrificed, or individual financial objections to the partnership plan.

From the patient's point of view, it may be said that the difference in efficiency is monumental. The percentage of error is minimized, and the patient very soon comes to realize that the arrangement is greatly to his advantage. From every point of view it must be conceded that the clinic plan is most advantageous to the patient, and at the same time it enables the doctor to make a long stride forward in the direction of professional advancement.

DR. HAVEN EMERSON APPOINTED

Dr. Haven Emerson, former commissioner of health of New York City, has been appointed medical advisor and assistant director of the Bureau of War Risk Insurance. The appointment of Dr. Emerson to this important post is in conformity with the policy of the Bureau of War Risk Insurance to select its headquarters medical staff from the civilian medical profession.

BOSTON CHILD WELFARE WEEK

PRACTICALLY every organization in Boston cooperated with the Public Health Committee during the week of February 8 to 12, inclusive, in a program demonstrating various methods of health preservation, especially as applied to children. Assuming a sound scientific basis for health movement, a constructive program was arranged to interest the public in the health betterment of children. School authorities extended a helping hand and

settlements and social workers exerted special effort to bring the parents to the exhibits and public meetings. The object of the campaign was to evolve a more permanent plan of work in the education of prospective mothers, and in relieving some of the health hazards that affect little children. The Committee on Health Education conducted an information bureau. Part of the demonstration was a health center equipped with nurses, physi-

cians specializing in the care of children, and dental hygienists. Parents were invited to have their children weighed and measured and advice was given as asked for on special problems. A social worker interested herself in securing help for parents when this was found necessary.

The Nutrition Committee sponsored exhibits from the school lunch department of the Women's Educational and

Industrial Union, from the Food Economic Kitchen, which supplied hot soup to some of the elementary schools, from Dr. William R. P. Emerson's nutrition clinic for delicate children; from the Boston Dispensary; from the Dietetic Bureau of the League for Preventive Work; from the Massachusetts Committee on Health in Industry; from the Nutrition Division of the State Department of Public Health; and from the Fathers and Mothers Club. Further features of the nutrition exhibit were ideal containers for luncheons that need to be carried, suggested meals for children, and nutrition panels from the National Child Welfare Association.

OCCUPATIONAL THERAPY

THE function of occupational therapy has long since passed the experimental stage and the efforts of those who advocate its use can now be devoted toward a better adaptation of the method to meet the special needs of the patient; for here, as elsewhere, the paramount consideration is the need of the patient, and whether occupational therapy be applied as a cure for "hospitalization"; a means of relieving the monotony of prolonged treatment, as in tuberculosis, so that real rest and not merely enforced idleness results; control gained of useless members; interest in life revived through new activities; or means of a livelihood so applied as to save the patient from hopeless dependency, the success of the method lies in it being prescribed and carried out in a manner that exactly fits the individual case.

The primary need everywhere is trained workers; great increase in facilities is called for; and personality studies must fit the measure to the patient psychically as well as physically.

Chronicity calls for methods of this kind in a marked degree. The commoner forms of chronicity, especially those common to adult life, and those which become progressively worse over a long period, it becomes a humane procedure as well as simplifies the problem of handling the hopeless to afford all possible activity and to open up as many channels of interest as possible.

In the so-called "functional disorders," like hysteria, neurasthenia, psychasthenia, chronic diseases of the joints, Bright's disease, diabetes, cardiac disorders—all affecting adults during the period when they are most important to their families—the economic aspect looms large. When the loss of wages extends over months and years, retraining in vocational lines has an added psychic value if the chronic invalid is thereby enabled to contribute to his care which extends over a long period.

The magnitude of the social aspect of the care of the chronic patient is not appreciated or our provision for the care of acute disorders would not be so complicated by the problem of finding adequate service for the convalescent.

Aside from any permanent value—economic or other-

wise—to accrue from occupational therapy, the measure would be justified as an aid in the crucial period between the acute stage of disease and the complete restoration of the invalid. Reports from tuberculosis sanatoriums show a much greater degree of persistence in treatment among these patients to whom occupational therapy is available, and in the cardiac child it enables the enforced rest which spells comfort or cure for the afflicted.

It is, however, in the re-education of the handicapped that results in restoring function and in making useful members of society out of physical derelicts that occupational therapy has received its recent impetus.

The loss to society of useful members who because of war injuries or other handicaps have suddenly closed to them all their customary channels of competition is largely countered by a system of therapy which not merely treats the injury but renews the interest, directs activities into new and productive channels, supports the personality, and builds character and resourcefulness while the process of physical restoration is going on.

The Montefiore Sanitarium at Bedford Hills, N. Y., devotes special care to finding avenues for remunerative employment of patients in whom tuberculosis has been arrested. The restorative occupational work is as far as possible directed toward retraining in a pursuit that will be safe and at the same time remunerative. The

workshops are light and well ventilated, the time allotment and general character of the work are prescribed by and are under the observation of the medical staff. The general efficacy of the method is reflected in the progress and contentment of the patients and the percentage who are willing to remain until they may be regularly and safely discharged.

S. P. M.

CHILD LABOR CONFERENCE

The Sixteenth National Conference on Child Labor will be held in connection with the Conference on Social Work June 22 to June 29, inclusive, in Milwaukee. A number of allied organizations will hold meetings in Milwaukee either immediately prior to or during the week of the Social Work Conference meeting. Among these organizations are: Public Health Nurses' Association, the Jewish Conference of Social Welfare, the Canadian Conference of Public Welfare, National Board of the Y. W. C. A., the National Association for Community Organization, Interstate Conference on Illegitimacy, National Probation Association, National Conference on Education of Backward, Truant, and Delinquent Children, National Children's Home Society, National Travelers' Aid Society.

HEALTH CONDITIONS EVALUATED

In a recent memorandum to the Ministry of Health in England, Sir George Newman emphasizes that there are five great reliable sources by means of which to evaluate the health condition of the people—the national health service, the school medical service, the health insurance system, the national service department, which, during the war, took stock of the physical condition of recruits and industrial workers, and the returns from the office of the registrar general, which are, in fact, the official vital statistics of the nation. By combining these sources of information, the condition of the population may be estimated in much more accurate fashion than ever before.

MOUTH HYGIENE BOOKLET

The September-October issue of the *Commonwealth*, the bulletin of the Massachusetts Department of Public Health, contains 356 pages devoted to twenty-two different phases of mouth hygiene activities, including an extensive bibliography on the subject. It is issued to promote uniformity in the activities in this field.

Keystone View Company, Inc.

Steam rollers, auto trucks, cannons and various toys to delight any child are made by the wheel chair patients of Montefiore Home and Hospital from discarded tin cans.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

GENERAL PATHOLOGY. By Dr. Ernst Ziegler. From the eleventh revised German edition, Gustav Fisher, Jena, 1905. Revised by Douglas Symmers, M.D.¹

One is so accustomed to highly recommend Ziegler's classical textbook on general pathology, that one hesitates in not giving full approbation of the last English translation of this work. This new American edition, however, is not only not up to the standard of previous translations, but falls far short of other American textbooks of pathology. This 1921 edition has not been brought up to date, as can be noted by a glance at the references given in the bibliography. On so important a subject as thrombosis, the most recent reference is dated 1906. It is a disappointment to find that most of the illustrations are crude line drawings characteristic of textbooks twenty years old. Illustrations of this sort are of no help in visualizing microscopic pathological anatomy. There are some more modern types of illustrations, but these fall very far short of the standard we are accustomed to in modern textbooks. Pathology, today, is far ahead of this textbook, and we cannot recommend this edition to medical students and practitioners. Dr. Wm. Thalheimer.

SURGERY, ITS PRINCIPLES AND PRACTICE. By Various Authors. Edited by William Williams Keen, M.D., LL.D., emeritus professor of the principles of surgery and of clinical surgery, Jefferson Medical College, Philadelphia, Vol. VII.²

During the past years of bloodshed many branches of surgery have undergone tremendous changes. The vast clinical material flowing back from the trenches carried with it innumerable lessons. No textbook embracing the field of general surgery could be complete without incorporating this recently acquired knowledge.

The seventh volume of Keen's surgery covers many of the subjects in which the greatest advances have been made. The chapter on the Treatment of Infected Wounds, with special reference to the Carrel-Dakin technique is an excellent summary of one of the greatest achievements of modern surgery. There is an admirable article on gunshot fractures. Chapter XXIII is a complete monograph on military orthopedic surgery by Sir Robert Jones and Hey-Groves. It is not possible in the small space allotted a review to dwell at length upon the various topics, suffice it to mention the subject of Nerve Injury and surgical repair, Blood vessel surgery, Blood Transfusion, the prophylaxis and treatment of Tetanus, Gas Gangrene and of Anthrax. Two chapters of a strictly military nature are, The Organization and Administration of the Medical Department of the Army, and Surgery on a Fighting Ship. A chapter of no less importance than those mentioned is one referring entirely to civilian life, namely Lovett's article on Orthopedics in Civil Life, emphasizing especially

our progress in repairing the ravages of infantile paralysis. The articles are written in a comprehensible manner, the text is profusely illustrated and well indexed.

Volume VII is a unit and although a logical addition to the preceeding volumes might well merit a title of its own. It will speedily find its way to the book shelves of the progressive surgeon.

There are still two important topics, outgrowths of war surgery, which are not covered in this book and which the reviewer hopes are taken up in Volume VIII namely the development of the treatment of empyema and the subject of lung surgery.

Ralph B. Bettman.

THE SCHOOL OF SALERNUM. The English Version. By Sir John Harington. History of the School of Salerno. By Francis R. Packard, M.D., and a Note on the Prehistory of the Regimen Sanitatis. By Fielding H. Garrison, M.D.³

This booklet has an interesting history that is woven about Salerno, the great center of medieval medicine. The poem which comprises the volume is one of the most famous literary survivals of the middle ages. The authorship of the poem, as the interesting preface says, is a matter of great dispute. Some consider it to be of composite authorship, whereas others attribute it to one man, who stood at the head of the faculty of Salerno at the time poem was written, probably the twelfth century. But, whatever the origin of the Regimen Sanitatis Salernitanum, the poem must have been quite popular as it passed through several hundred editions, was translated into many languages, and served at one time as a standard textbook of medicine, and later as a handbook of domestic medicine. In its present form, which is the English version of Sir John Harington, an attache of the court of Elizabeth, compiles not only the unique poem and notes for its elucidation, but also a complete and fascinating history of the school of Salerno and a scholarly description of the historical background of the poem by Dr. Fielding H. Garrison.

I. P. L.

COMMON INFECTIONS OF THE KIDNEYS WITH THE COLON BACILLUS AND ALLIED BACTERIA. Based on a course of lectures delivered at the London Hospital by Frank Kidd, M.B., B.C. (Cantab.), F.R.C.S. Eng. With an additional lecture on the bacteriology of the urine by Dr. Philip Panton, clinical pathologist, London Hospital.⁴

The book before us dealing with common infections of the kidneys is one which should find a place in the library of many physicians. It is a practical, logical exposition of an interesting subject. All essential points are brought out and the size of the volume and arrangement of the text make it a convenient and ready reference book.

GREAT BRITAIN.....SCIENCE REVIEWS, Ltd.
36-38 Whitefriars Street, Fleet Street, London, E. C.

AUSTRALASIA.....STERLING & CO
Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th of the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

THE RADIOGRAPHY OF THE CHEST. Vol. 1, Pulmonary Tuberculosis. By Walker Overend, M.A., M.D. (Oxon), B.Sc. (Lond.)⁵

There is a tremendous amount of information to be obtained from careful study of this book. Casual reading of it is impossible as neither the style nor the arrangement is easy to follow. However, the contents fully repay one for careful reading through the volume.

THE OXFORD MEDICINE. By Various Authors. Edited by Henry A. Christian, A.M., M.D.; and Sir James Mackenzie, M.D., F.R.C.P., LL.D., F.R.S. Volume III—Diseases of the Digestive System, Kidneys, and Ductless Glands.⁶

The volume deals with the stomach, intestines, peritoneum, liver, pancreas, and some of the ductless glands. It also contains a discussion of nephritis by Dr. Christian. This discussion stands out as an up-to-the-minute presentation of a subject that at the present time is certainly difficult to write about, but Christian seems to have maintained an attitude of judicious skepticism, and to have presented the matter in a logical, clear, and simple manner. The contributions of Rehfuess and of Sippy are interesting, but it seems to the reviewer that they would have added to their value had more extensive bibliographical references been used.

THE NERVOUS HOUSEWIFE. By Abraham Myerson, M.D.⁷

"The Nervous Housewife" is a patient who is seen very frequently in the private office or the wards of a general hospital. She is seen probably much more frequently than she is recognized for under the cloak of her numerous symptoms she is very apt to hide the real cause of her complaints. Myerson's book is an unusually interesting, popularly written discussion of this lady. Reading as it does almost like a novel, the scientific references seem sound throughout. Strange to relate, a modern neurological book written popularly is not Freudian.

THE CHEMISTRY AND ANALYSIS OF DRUGS AND MEDICINES. By Henry C. Fuller, B.S., in charge of the Division of Drug and Food Products, Institute of Industrial Research, Washington, D. C.⁸

The analytical chemist is often confronted with the task of identifying a mixture containing some of the more rare drugs. To do this it was often necessary to go through a vast amount of literature found in various texts and journals, to spend a large amount of time previous to the actual analytical work. With Fuller's book on hand, this problem is solved. The book gives methods for the identification and estimation of drugs, it lays special emphasis on the official methods used by the Government laboratories, a feature which is of value in case of court proceedings. A set of methods for drug assaying is included in the text.

The book is well arranged. A more thorough citation of foreign literature might have been of additional value.

A COMPEND OF DISEASES OF THE SKIN. By Jay Frank Schamberg, A.M., M.D.⁹

A handbook on diseases of the skin is an indispensable volume for the bookshelf of the busy physician, a need supplied by this excellent little book which for ready reference and quick use has a distinct field.

What the Air Does to Us

By ELLSWORTH HUNTINGTON, PH.D., YALE UNIVERSITY, NEW HAVEN, CONN.

THREE things, and only three—food, water, and air—may be considered as absolutely essential to human life. The chief difficulty of primitive man was with food. He usually lived where the air was neither excessively hot nor extremely cold, and he breathed the pure, unheated outdoor air. He drank of the running brooks and springs which almost never were contaminated. Thus his supplies of air and water were the object of no special concern to primitive man and were the source of no great inconvenience. But food was hard to procure. For untold ages man's supreme effort was to procure food enough for himself and his family. Despite his efforts he was in immediate distress whenever the beasts of the chase were scanty, or when for any reason there was a dearth of fruits and nuts, and other food products. Thus, under primitive conditions, where one person died from bad air or poor water, probably a score died from lack of food.

But the time came when there was a great reversal in the relative rôles of air, water, and food. Man branched out into highly diverse climatic regions; he multiplied and filled the earth; and he learned to build for himself tight houses that keep out the air, and that can be warmed by means of fires. Today the results of this change are perhaps at a maximum in countries such as China, where millions of people die because for months each winter they shut themselves up in warm, unventilated houses. Other millions die from dis-

eases which have their source in an impure water supply. This number would be still greater but for the fact that the Chinese have acquired the almost universal habit of using tea and have incidentally gained thereby an advantage in the use of boiled water. Lack of food is also responsible for an enormous percentage of deaths in catastrophies like the famine which is now devastating China. A hundred thousand years has brought that country to a point where she is scarcely better off than was primitive man in respect to food, and is in far worse straits in respect to air and water.

Conditions Here Improving

Though in many respects our own condition is no better than that of our ancestors of ten or a hundred thousand years ago, the reversal from primitive conditions has here progressed farther than with the Chinese, and we are now on the upward road. The amount of suffering in the United States from scarcity of food is negligible, although much harm arises from the lack of a sufficient variety, from poor cooking, from overeating, and from other abuses. Nevertheless the amount of distress and death arising from this source is vastly less than among primitive peoples, or in China.

Much the same state of affairs obtains with regard to drinking water. The deaths which may still be charged to typhoid, dysentery, and other water-borne diseases are relatively more numerous than the deaths

from such causes among our primitive ancestors, for the modern density of population is against us; but almost all communities in the United States are awake to the necessity of supplying an abundance of the purest kind of water.

With air the case is different. Where one man among our primitive ancestors died from the effects of improper air, perhaps a dozen or a score die among us. For example, in cities the death rate sometimes rises 50 per cent during a hot wave; and the health and efficiency of an ordinary community in the northern United States in winter is by actual measurement anywhere from 10 to 30 per cent lower than in the late autumn or the late spring, a condition which could be greatly mitigated if everyone understood and applied the true principles of the use and care of the air.

Air to Be Used

The words "use and care" are employed advisedly. Although the air comes to us without cost, it is something to be used and cared for as carefully as food and drink. The great principle that should govern our use of the air is that of the *optimum*. The optimum is the most favorable condition. Each living species has a definite optimum in respect to all sorts of conditions. Thus the optima for a certain fish may include a temperature of fifty degrees, an abundance of small cephalopods for food, a low percentage of salinity, a slow but steady movement

of the water, and a relatively high percentage of dissolved oxygen. In no one place do all these optima prevail at any one time; therefore the fish seeks the region where the greatest number of conditions approach the optimum and none is extremely far from it. Often by migrating with the seasons the fish can keep much more nearly in the best combination of optima than if the animal remained continuously in one place.

Man, unlike the fish, can create his own optima, and in progressive countries he is rapidly doing so in respect to food and drink, and more slowly in respect to the air. The chief atmospheric optima relate to (1) temperature; (2) purity; (3) movement; (4) humidity; and (5) variability. These are not mentioned in the order of their importance, but according to the degree of attention which they commonly command.

Temperature undoubtedly comes first on both counts. The optimum temperature, taking the average for day and night together, is about 64 degrees F. It may vary a little for individuals; age makes some difference; so does the climate in which people have grown up; and there appears to be a slight difference according to race and occupation. The most surprising fact about the optimum temperature, however, is the slightness of these differences. Whether dealing with babies in Paris, adults in Sicily, factory workers in New England, Cuban cigar makers in Florida, Negroes in Virginia, or white people in Finland, the optimum never ranges below 60° or above 68°. Other conditions may of course cause people's health and strength to be greatest at some other temperature, but that is not the result of temperature. By and large it is established beyond question that an average of about 64° is the best condition for people of European origin. This means that in the rooms where people live and work the temperature may range up to 68° or down to 60°; it should never, however, remain above 68° any longer than is absolutely necessary. Higher temperatures impose a strain upon the heart and actually raise the temperature of the blood; their effect is like that of a mild fever. Of course people must be comfortable, and in winter many are not comfortable unless the thermometer stands at 70° or higher; but that is merely because the humidity is not at the optimum. Our great mistake in respect to temperature is that we act as if it were the one essential condition of the air, and also

as if there were no harm in high temperature but great harm in low. As a matter of fact, either extreme is bad, but in the United States far more harm comes from temperatures that are too high than from those that are too low.

Every one realizes the importance of pure air, but in practice we do not begin to take pains enough in this respect. Absolute purity is of course the standard. How important this is may be judged by comparing winters when there is plenty of snow with those when the ground is bare. This was well illustrated in 1919-20, a winter that was extremely cold in the eastern United States, so that the death rate would normally have risen very high. A cover of snow for many months, however, by preventing the air from being dusty and full of germs, materially lowered the death rate.

The Air Should Move

It is well recognized that movement of air is highly important. Air that seems quite impure and foul, or that is too hot and moist does less harm when moving than does much better air when stationary. One of the great reasons why we are behind primitive man in our relation to the air is that he was not skillful enough to shelter himself from moving air, while we have developed the false idea that the air in our houses should be almost motionless. While drafts are to be avoided, there can be a constant and considerable movement of the air without creating a draft.

One reason why Americans have such a superstitious horror of drafts is that we have not yet learned the importance of atmospheric humidity. Every one knows that extreme moisture is bad in hot weather, but it is not so generally appreciated that abundant and exact observations show excessive dryness to be bad also. In the long run, Americans suffer vastly more from dryness of the atmosphere than from too much moisture. Moisture in the air is important in three respects: (1) The human lungs function best and can most easily regulate the temperature of the body when the air contains about five grains of water vapor per cubic foot. This means a relative humidity of about 100 per cent at a temperature of 56 degrees; about 75 per cent at 64 degrees; about 65 per cent at 70 degrees; and still less at higher temperatures. (2) Under ordinary conditions moist air is less dusty than dry. (3) If the air contains the right amount of water vapor, the evapora-

tion from the skin at temperatures of 64 to 68 degrees is relatively slight, yet, sufficient, and, as a consequence, people feel as warm in a temperature of 65 degrees within doors on a winter day as they do ordinarily at 70 degrees or more when the air contains only about one-fourth as much moisture as it should. In the same way, if the air of the right temperature contains the right amount of vapor, a gentle movement does not chill people as does a similar movement of dry air. Thus the correct amount of moisture is not only of direct benefit to the lungs and to the mucous membranes, but is a help toward achieving the optimum of purity, temperature, and movement.

Variability of temperature and probably of other conditions appears to be highly important. Although the matter has not yet been thoroughly studied, this much is clear:—So far as exact studies have been made, they show that while extreme variations may do harm, mild variations are distinctly stimulating. If the temperature of the air falls a little, almost every one is stimulated and begins to work harder. A rise of temperature has an opposite but less marked effect. Hence the net result of moderate changes, both indoors and out, is to improve people's health and make them work harder.

Other atmospheric conditions, such as electricity and light, also play a part in determining the health of the nation. For our present purpose, however, the great outstanding fact is that by shutting ourselves up in houses and by emphasizing protection against low temperature as if it were the only harmful climatic condition, we have put ourselves in a position where our relation to the air is vastly worse than that of the primitive ancestors whose susceptibilities we still inherit, or than our own position in respect to food and drink. Some day our aim will be not merely to warm our houses in winter, but to fill them at all seasons with pure air having the optimum temperature, the optimum humidity, and the optimum variability and movement. When that is done, many of the weaknesses and ailments that spring from our modern indoor life will be greatly mitigated.

Censorship Laws for Movies

Censorship laws for motion pictures have been passed in Pennsylvania, Ohio, Kansas, and Maryland. Nine other states have had bills defeated; in nine legislatures the bills are pending.

Exercise Prescribed for the Individual

Precision is as Important in Prescribing Exercise as in Any Other Form of Therapy

By FLORENCE L. MEREDITH, M.D., ASSOCIATE PROFESSOR OF HYGIENE, WOMEN'S MEDICAL COLLEGE OF PENNSYLVANIA, PHILADELPHIA, PA.

ALTHOUGH we have had gymnasiums in our midst for many centuries, there is one aspect of the utility of which we take advantage to a very small extent. We do not use them for the purpose of teaching individuals special individual exercises, needed in their own cases either for the cure of functional disorders which seem imminent, or, best of all, the building up of the sort of health which in their individual cases puts any maladies, organic or functional, farther away.

Not Confined to Orthopedics

We have utilized the gymnasium, although to a much less extent than we should, to provide general exercise to individuals in groups, and when we have used it for individual purposes it has been largely to correct certain postural and anatomic defects. Gymnasium means to the average physician and layman alike a place where the individual is put into a class and does stereotyped series of exercises, progressing from beginner's to advanced grade, the only differentiation among the members of a class usually being in amount rather than in kind of exercise. Corrective gymnastics, in the same way, means to most people the correction of such conditions as scoliosis, or defects ensuing after paralyses, fractures, sprains, and the like.

There is nothing whatever to be said against the utilization of the gymnasium for both these purposes; in fact, they should be used a hundred or a thousand times as much as they are

now in that way. But to omit the use of the gymnasium for the three purposes mentioned above to meet individual needs is deliberately to deprive ourselves of a health measure which would add very greatly to our armamentarium.

The burden of my suggestion is that individual as well as group exercise be offered in every gymnasium, and that these individual exercises include not only "correction" as it is now understood, but also correction of many functional physiological conditions. We should also go more nearly to the root of the matter in each case, trying to use individual exercise for the prevention of possible ill health, and especially for the con-

Underwood & Underwood
The art of self-defense is taught girls at the University of Cincinnati who expect to become physical culture teachers, an art which could well be extended to all co-eds.

struction, out of the individual material, of health.

Limitations of Group Exercise

It is quite obvious that there are advantages pertaining to group exercise which have made it so long popular, and that some of these advantages do not hold in individual work. Chief among these is the arousing of the group spirit, by which the individual in company with others doing the same thing, is spurred on as he would not be alone. There is probably no spirit more desirable to foster in our democratic country than that of together-ness. Every way in which this urge can be evoked and each individual made to feel like a member of a great whole striving toward a great end, should be en-

couraged. It is for this reason that sports are particularly desirable. The fact of playing together in unity and yet in competition, which has its counterpart in the business and political life of the country, or should have, makes "sports" of individuals,—and if each and every individual had somehow acquired the spirit described by the word "good sport," our problems of many kinds would cease.

In group gymnasium work, however, an individual may be spurred by emulation to do too much, and his health may suffer accordingly. All individuals certainly have not the same needs, and they are not even near enough alike for it to be safe to put them in the same class in the gymnasium. What is one man's meat may be another man's poison. Fortunately, the individual who goes to gymnasium usually has sufficient judgment not to carry the work too far,—but he may. Then, again, if he tends to do this excessive work, the watchfulness of the teacher may intercept him,—but it may not. The person may not be wise and the teacher may not be watchful, and the result may be overdoing. If the result is, as it might easily be, impaired health, the gymnasium will suffer the consequent loss of good standing with that individual and perhaps many others. We have to make sure that each individual gets what he comes for, better health, or we are risking the good name of our gymnasium.

Underwood & Underwood
Outdoor games are employed at the Florida State College for Women at Tallahassee. Baseball, swimming, and other outdoor games constitute the required course in physical education.

Underwood & Underwood
Army Red Cross nurses in a tug of war during the Mosier Athletic Carnival at the United States General Hospital No. 41, Fox Hills, Staten Island, N. Y.

This group of girls at Castle School, Tarrytown, N. Y., are playing "cage ball," one of the many physical culture games invented by Dr. Emmett Dunn Angell. Here health and strength accrue from games in which only the fun is thought of.

On the other hand, the individual who is put into a class may not receive any impetus at all. Being still a free agent, although under the strict eye of the instructor, he or she drops out of first one and then another exercise, or perhaps stands up against the wall and does not even begin, or may go through the motions of exercise without putting any energy or effort into it. We have found among girls a great degree of shyness about appearing at a disadvantage among the other girls. Rather than not do a thing well they will not do it at all. The other girls may not have had any more gymnasium experience, but get along better because of their lack of shyness and because of individual variation in muscular development and the knack of using muscles. Sometimes it is the gymnasium suit which causes the shyness. They may be ashamed of their scrawniness or plumpness as the case may be, but it is usually their inability to show off in muscular ways and the resulting self-conscious awkwardness. Their stay in the gymnasium is usually quite brief. The teacher herself, by calling attention to them, as she often must for the sake of class discipline, often precipitates their leaving. But the teacher may tactfully hold them through the season, knowing that they are not getting anything from the gymnasium, yet hoping against hope that they will develop in time. Of course, their failure to get any better health out of the gymnasium will be charged

to the gymnasium, or perhaps the teacher, or gymnasiums as a whole, and exercise per se will be incriminated.

Unsuited to Class Work

There are thus two classes of persons who are not suited to regular classes, those whose physical condition is such that they should not be over-stimulated, and whose mental condition is such that in a class they are sure to be; and those who ought to be more stimulated, but are too shy and too afraid in a class. One type gets too much out of a gymnasium class, to its detriment, and the other type too little, equally to its detriment. This applies equally well to those who have no special needs of any kind, and who have no special defects to be considered, those who would be called average, and who are not greatly harmed either by too much or too little exercise. But the absence of actual harm does not mean that the gymnasium has done its part, for its function is not discharged until actual good has resulted.

When we come to the large number of individuals who, while apparently up to the average, are as a matter of fact likely to be harmed by one or another kind of gymnasim work, it is quite another matter. Among girls, with whose physical culture I am most familiar, this variety forms a large percentage of those I examine. They have definite needs in the way of exercise,—a certain amount and variety being positively indicated, and

any other amount and variety being positively contra-indicated. These girls cannot be put into classes safely until the physician who examines them, the physical director, and the girls themselves know what is beneficial, what can be done and what should not be attempted. In the case of these girls, if it were a choice of individual exercises or class exercises, the former should always be chosen; but let me add quickly that, if it is a choice of class exercise or no exercise, the chances are about twenty to one that the average girl, even with special needs, will be more harmed by no exercise than by judicious class exercise. This applies even to many heart cases, and others of equal seriousness. Those who have been exercising freely, even unguided, invariably show up better than those who have been doing nothing. We are discussing here, however, only the relative advantage of individual or group work.

I am often reminded of the old days when in the springtime a mixture was made of sulphur and molasses, and every child, and grown-up, too, was treated to a nasty spoonful every morning "three days running and three days skipping." We now omit the sulphur and molasses, but the way we prescribe the gymnasium, the same amounts, the same time of year, regardless of individual needs and consequences, because it is "good for what ails you," sounds very much like the old empiricism of the laity. There is no precision or sound reasoning about it, and no possibility of ob-

A high school girl at Roxbury, Mass., clearing the bar in fine style at the annual field day of the practical arts.

taining accurate results. We have all said for years that gymnasium exercise helps people, yet it would be difficult for most doctors and physical directors to show what percentage of people are helped, what kinds of people are helped the most, and in what ways and in what degree.

Prescribed Exercise

In order to get away from generalities and show exactly what can be done by a gymnasium and how, it will be necessary for us to study each individual case more accurately, and prescribe exercise as we do other health and therapeutic measures. The first requirement before we can fully appreciate what happens in the case of each girl is, by means of a complete medical and physical examination, to find out all we can about her before she is put into the gymnasium. This is the only scientific way of making use of formal exercise. It may be said, and has been said, that on this theory a physical examination should be taken before one does anything at all in the world, for general gymnastic work is no more likely to do harm if indulged in indiscriminately than are all other activities included under getting a living and having a life. This is quite true. The time will come when individuals will not feel so free to go ahead on their own initiative, unguided by a knowledge of where they stand in health and in what direction the proposed activity will take them. Already examinations before entering schools and industrial positions are very popular, for this reason. It will in time be seen that the advantage of this forehanded knowledge is a very great one. But because we cannot at present carry it out in the commencing of every sort of activity, we can at least carry it out in a field as particularly and closely related to health as the gymnasium. The examination should include the following observations:

The next need, after the physical examination of the applicants, is plenty of well trained physical directors. One teacher with a dozen large classes can do better work if her pupils are sent to her examined and partly classified, but she cannot arrange her work so as to include much personal work. If the organizations conducting gymnasiums were to realize that part of their essential

equipment is not one director, but a number, it seems to me that the public would gladly pay for them, as for all other essential equipment, as they would expect to pay for thorough examinations. Even admitting it not to be essential in order to have the gymnasium do good work, it can be pointed out that a gymnasium plus five physical directors is worth very much more than five times as much as with one. In fact, five, or whatever may be the full number needed to do all the necessary individual work, will make the gymnasium an important factor in the health of any community, whereas, under-manned, it might have had relatively inconsiderable value. If the gymnasium can make an impression on the health of the community, as it will if individual work is properly done, the public will early recognize the fact and be eager to pay the increased cost, instead of being, as they now often are, loath to pay the lower cost.

Summer School for Social Workers

The Smith College Training School for Social Work announces the program for the summer session, July 5 to August 30, covering psychiatry and medical social work as well as community service. Prof. C. G. Woodhouse gives a course in industrial problems, Prof. Kimball, in government as a factor in social work, and Dr. Williams and Dr. Houston, social psychiatry.

World Health and the Rockefeller Foundation

Disease Disregards All Boundary Lines, and So Does Pure Science in Tracing Cause and Effect

By GEORGE E. VINCENT, PRESIDENT, THE ROCKEFELLER FOUNDATION, NEW YORK CITY

THE Rockefeller Foundation was chartered in 1913 "to promote the well-being of mankind throughout the world." While thus broad in its possible scope, the Foundation has restricted its activities mainly to medical education and public health. In order to accomplish lasting results, specialization is necessary, since small sums spent on a multitude of objects relieve but do not remedy. The International Health Board, the China Medical Board, and the Division of Medical Education are agencies created by the Foundation to administer different phases of its work.

Public Health and Education

The methods employed are demonstrations carried on in cooperation with governments and educational institutions, or contributions to carefully prepared plans of development. The aim is not permanently to assume government functions, but either to convince established agencies that certain policies and procedures are both effective and feasible or to aid them to extend and strengthen their work.

The control and prevention of hookworm, malaria, and yellow fever, a campaign against tuberculosis in France, the improvement of local and national health administration, the professional training of public health officials, studies of various problems in preventive medicine, aid to medical schools in the United States, Canada, England, Belgium, China, Brazil, emergency aid to medical schools of Central Europe, University fellowships in public health and modern medicine for students, are the leading features of the present program of the Rockefeller Foundation.

Hookworm Control

First in point of time among the diseases to be dealt with by the International Health Board of the Rockefeller Foundation, hookworm disease still remains its chief activity so far as area covered, funds expended, and personnel employed are concerned. The disease is widely prevalent in tropical and semi-tropical regions. The typical methods em-

ployed include a preliminary survey to determine the degree of infection, the organization of dispensary units for treating the population, the carrying on of educational campaigns, and the introduction of sanitary procedures which will prevent the pollution of the soil and the reinfection of the people.

Although hookworm control is in itself an important end, the Foundation has from the outset regarded these campaigns as chiefly a means of educating communities in the possibilities of public health. Having achieved this aim,—the development of permanent agencies and county health organizations capable of assuming entire responsibility for carrying on the work—the Foundation plans an early withdrawal from hookworm activities in the southern states of the United States. In many places, notably in Brazil, Australia, and some of the southern states of the United States, hookworm control has expanded into general programs of sanitation and preventive medicine.

Eradicating Yellow Fever

In 1916 General William C. Gorgas, well known for his achievements in the sanitation of Havana and of the Panama Canal Zone, headed a Yellow Fever Commission under Foundation auspices to Central and South America. After first hand investigation the Commission reported that the seed beds of yellow fever were limited to a few centers: Guayaquil in Ecuador, Merida in Yucatan, suspected areas between Pernambuco and Bahia in Brazil, and possibly certain regions on the west coast of Africa. The Commission recommended that an attempt be made to eradicate yellow fever from these endemic foci. Arrangements had been made early in 1917 to undertake this task, when the entrance of the United States into the war compelled the postponement of the plan.

Yellow Fever Germ Discovered

In 1918 General Gorgas retired as Surgeon General of the Army and assumed the directorship of the yellow fever campaign of the Rockefeller Foundation. As a preliminary to

practical field work, a special commission was sent to Guayaquil to investigate the causes of yellow fever. Dr. Hideyo Noguchi of the Rockefeller Institute for Medical Research was the bacteriologist of this Commission. He made a series of experiments and investigations which resulted in the isolation of a minute organism to which he gave the name *Leptospira icteroides* or "slim spiral, the jaundice maker." Later experiments in Yucatan, Guatemala, Salvador, and Peru have confirmed the results of the investigations in Guayaquil, so that it seems altogether likely that the germ of yellow fever has been identified. A serum and a vaccine prepared as a result of these researches have so far given encouraging results.

Campaign in Guayaquil

Field work in Guayaquil was undertaken in December, 1918. A systematic and thorough attack upon the breeding places of the *Stegomyia* mosquito was undertaken. During 1918 more than 450 cases of fever had been recorded. As a result of anti-mosquito measures the number of cases fell from 88 in December, 1918, to 37 in February, 1919, to 13 in March, and to zero in June.

Extending the Fight

A representative of the Foundation visited the east coast of Brazil, where the Brazilian government is dealing with sources of infection in the region between Pernambuco and Bahia. The complete elimination of yellow fever from Rio de Janeiro some years ago shows that the Brazilian sanitarians are familiar with yellow fever control and may be counted upon to carry out their part of the world campaign.

In the summer of 1920 a commission under Foundation auspices headed by General W. C. Gorgas set out for Africa via England to investigate a disease which had been reported as yellow fever in certain areas in the vicinity of Lagos on the west coast of Africa. While in England General Gorgas was taken suddenly ill and never recovered.

After the death of General Gorgas,

General Robert E. Noble sailed for Africa at the head of a group composed of Dr. Juan Guiteros of Brazil, Dr. A. E. Horn of British Colonial Service, and Dr. W. H. Tytler of the National Institute of Medical Research, London. Dr. Adrian Stokes of Dublin, who had previously worked for a few weeks with Dr. Noguchi at the Rockefeller Institute for Medical Research in New York, served as bacteriologist to the expedition.

The Commission found that cases of yellow fever were rare and mild. It concluded, however, that the malady had been both epidemic and endemic in this region and that its epidemicity was greater than any official report would indicate. Plans are under consideration for an extended study of yellow fever in Africa as recommended by the Commission.

Because of unsettled conditions in Mexico, the inauguration of the work in that country has been delayed. However, the Foundation has now accepted the invitation of the government of Mexico and members of the Foundation staff are cooperating with local authorities in an active campaign against the disease in the last of the endemic centers. Through the cooperation of Central American countries, the spread of yellow fever from southern Mexico has been checked and the danger of an outbreak seems to have been averted. It is hoped that the institution of control measures will put an end to dangers of infection from Yucatan and southern Mexico.

Attacks on Malaria

For the last four years under International Health Board auspices experiments in malaria control have been carried on in Arkansas and Mississippi. Demonstrations in eight different communities have shown clearly that it is possible to control malaria at an installation cost of about one dollar per capita and at a maintenance expense of about fifty cents per capita. Practical measures for combating malaria consist in eliminating mosquitoes, screening houses against them, and in sterilizing malaria carriers by means of quinin. In a given case one or all of these methods may be used, according to local conditions. During the summer of 1920, in cooperation with the United States Public Health Service, state boards of health, and local authorities, demonstrations in malaria control were conducted in forty-four different towns in ten southern states. Experiments in malaria prevention have recently been extended

to typical tropical regions by the inauguration of malaria control measures in Nicaragua.

Cooperating in West Indies

Hookworm relief and control measures in the West Indies have included surveys and field operations in Antigua; cooperation with government and with planters' associations in British and Dutch Guiana, and typical control programs in Grenada, St. Lucia, and St. Vincent. Surveys in Trinidad showed 75 per cent of the population infected. The Government adopted stringent sanitary regulations which are proving effective. In Jamaica a survey was made in 1918 and control measures inaugurated last year. The Government is enforcing sanitary laws strictly. Surveys have also been made in Porto Rico, Santo Domingo, Barbadoes, and Cayman Islands.

Other states of South and Central America, including Brazil, Costa Rica, Guatemala, Nicaragua, Panama, and Salvador, have been surveyed and have instituted remedial measures.

In the Far East and Africa

The Far East has not been neglected. In Ceylon 98 per cent infection was discovered among the estate laborers. This has resulted not only in curative measures but in radical improvement in sanitation. Surveys in Papua and in Queensland have led to a large undertaking which is likely to extend to the whole of Australia. A cooperative five year program has been adopted which aims at activities in the entire field of public health. In the Madras Presidency of India a hookworm campaign has been carried on during the past year. Since February, 1918, control measures have been under way in the Seychelles Islands, the Federated Malay States, in Java, and in Fiji. From 1913 to 1915 hookworm prevention was undertaken in Egypt. As a result of war conditions, this work was abandoned. Surveys or actual operations have been made or planned for Mauritius, Borneo, Straits Settlements, Tonga Islands, and Tobago.

Training Health Officers

The need for an expert personnel early impressed the officers of the International Health Board with the necessity of training persons to supervise and administer public health work. The Foundation has therefore provided funds for establishing at Johns Hopkins University in Baltimore, a School of Hygiene and Public Health in which a thorough train-

ing is being provided. Not only are essential laboratory and research facilities offered, but arrangements are made by which practical training in the field is secured under the auspices of city, state, and federal health departments. A number of fellowships for men who desire to enter the field of public health service are given. Among the fellows are representatives from thirteen separate governmental areas, including Canada, Mexico, Brazil, England, France, Belgium, China, and Czecho-Slovakia.

Medical Education

The interest of the Foundation in public health has led logically to a concern for fundamental medical education. It is obvious that the progress of preventive medicine is dependent not only upon the training of public health officers, but upon the attitude of the medical profession in general toward prevention of disease. The Foundation, in cooperation with the General Education Board, also established by Mr. Rockefeller but limited by its charter to gifts within the United States, has made appropriations to the University of Chicago, is establishing a modern medical center in Peking, and has made liberal grants to medical education in Canada, England, and Belgium, and has plans for aid to medical education in other parts of the world.

Medical Center in China

The China Medical Board administers the work which is being established in China on a rather generous scale. The Peking Union Medical College has a hospital, an out-patient service, ample laboratory facilities, a pre-medical school for the preparation of students, and a teaching staff of foreigners and of Chinese who have been well trained in the United States, Canada, and Europe.

The aims of the college are to offer a thorough education for general practitioners, graduate courses for the training of teachers, investigators and specialists, and brief courses for medical missionaries and other physicians. Opportunities for medical research, especially into diseases peculiar to the Orient, will also be provided. Attempts will be made to promote a general knowledge of the spirit and methods of Western medicine and the importance of preventive medicine. Aid is being given to a number of hospitals in different parts of China and fellowships are being granted both to Chinese students and to missionaries on furlough, in order that they may pursue

advanced courses in Western University medical centers.

Canadian Medical Schools

In accordance with a suggestion of Mr. John D. Rockefeller in connection with a recent gift to the Foundation, a preliminary survey of medical education in Canada has been made with a view to the distribution of five million dollars to certain medical schools in the Dominion. Gifts amounting in the aggregate to three million dollars have been made to the medical schools of Dalhousie University, Halifax; McGill University, Montreal; University of Toronto, and University of Manitoba, Winnipeg. The University of Alberta, Edmonton, and the Université de Montreal are being given aid on a yearly basis while their medical schools are in process of reorganization.

Aid London Medical School

To enable the University of London to cooperate with the University College Hospital and Medical School in increasing facilities and endowments and in unifying more closely

on the same site the laboratory and clinical facilities needed for a thoroughly modern medical school, the Foundation has made a gift of approximately five million dollars. This will be used for an Institute of Anatomy, an obstetrical unit, a nurses' home, the remodeling of the present hospital, and also for providing a substantial increase in annual maintenance.

Reorganization in Brussels

The Foundation has recently announced a gift of \$3,500,000 to the University of Brussels to enable it to carry out a plan of thorough reconstruction and reorganization. A municipal hospital will be entirely rebuilt, laboratories now two miles away will be housed in new buildings on the hospital site, a nurses' home and training school will be built, additional endowment provided, and an entirely new régime inaugurated. A group of able medical teachers, the hearty cooperation of the municipality, and the loyal approval of the public make the outlook most encouraging.

The war against disease is a world war. Commerce carries dangerous infections as well as goods and ideas. The health problems of the remotest land concern all peoples. More and more nations are coming to recognize their interdependence in health as in industry, government, science, and culture. There are even now foreshadowings of world wide cooperation in combating the maladies which have long threatened humanity. For this new campaign leaders are needed to extend the frontiers of medical science, to teach, to organize, to administer.

Demonstrations are required to convince communities and nations that diseases can be controlled and even eradicated. The Rockefeller Foundation, enlisted for this world wide campaign against disease, is cooperating with many agencies in five continents, hopes to foster the growth of international confidence and good will, and is thus seeking the fulfillment of its chartered purpose—"to promote the well-being of mankind throughout the world."

What Is a Health Center?

By E. A. PETERSON, M.D., NATIONAL DIRECTOR, HEALTH SERVICE, AMERICAN RED CROSS, WASHINGTON, D. C.

DEFINITIONS of the Health Center are as numerous and varied as the kinds of health workers who have come in contact

was associated, and has used it accordingly. This widespread use of the health center in many different ways is a testimony to the value of

influences radiate, a place where the health of the community is studied and promoted." That is a good definition but stated in too general terms.

The one room health center groups its educational, informational material to meet the requirements of ready use. It is a clearing house which everyone uses.

with this form of health organization. In accepting the idea each worker has described it in terms of the particular phase of health work with which he

the health center as a health institution.

Someone has stated that "the health center is a place from which health

The health center, having a definite rôle to play in the health field, ought to be more explicitly defined. This is an attempt at such definition. It

must be kept in mind that the term "community health" covers the field in which all the health agencies—health officers, private physicians, schools, hospitals, sanatoriums and private health agencies—function usually independently. It is broader

community health interest—down to single rooms which are still expressions of that interest and forerunners of more adequate quarters.

Functions of Health Center

Functionally, the health center is

their services and information. It is probably true that most communities are getting "less than half the service from existing health agencies that these agencies could and would render." It is also true that there is some duplication of work.

The Public Health Center consolidates, administers, and increases efficiency in the Department of Social Service.

Day and evening clinics provide that all classes of the people may have access to the service.

than the field usually included in the term "public health."

The Physical Health Center

Physically, the health center is a building, rooms, or room, centrally located in the community. The center may contain the offices of all the health agencies operating in this district, the health department, medical and dental societies, school medical inspection, and such private health agencies as the Visiting Nursing Association and the Anti-Tuberculosis Society. It may include clinics operated by any of these agencies. It also may include equipment for demonstration and education in health matters.

On the other hand, the health center may be a single room where information on health is dispensed—information which aims to put the people of the community in touch with their health facilities—and where the community is organized to study and promote its health work. It is conceivable that the health center idea can be promoted without the central building or rooms, but experience has shown it to be so much easier to work out the idea from a physical center that one should always be established. The provision of such a physical center saves the time, expense, and energy of all concerned—the health agencies and the public.

At the present time these physical centers range from huge memorial buildings—beautiful expressions of

an institution through which the community may get in touch with all health promoting agencies and with the health problems of local and of national importance.

There are at the present time four great health forces operating in any community; these are, (1) the legally constituted authority, (2) the private practitioner, (3) the schools, and (4) national and local private health agencies. All of these forces are operating independently—so far as authority is concerned—towards better health for the community. Each has a field more or less clearly defined. The health center is a point of contact between the community and these agencies. It offers an information service, free to all, which puts any person in the community in touch with the agency he especially needs. It describes and pictures to the community the services available from all the agencies operating there, and it pictures to the public the health needs of the community as they are seen by the health agencies operating there. It is an institution for "health education" in the broadest sense of the term. The health center makes special effort to supplement the work of existing health agencies, enlisting in those phases of health work which can be done by volunteers the members of the community who have time and aptitude for such work. The health center is an institution through which the existing health agencies may bring close to the community

By and large, community health agencies give to the community just about what the community will accept. The health officer is usually a little bit better officer than the community wants him to be and the doctor a slightly better practitioner than the community demands. Both assume leadership, but do not dare get too far ahead of the community. Both want to see the community demand a higher type of health work, or at least permit a higher type of work. Each has made attempts to bring this about, but always as health officer or doctor; and too often the attempts failed because the community looked upon them as "partisan" movements.

The health center representing the health interests of all concerned—that of the community as well as those of technical health workers, and the community often *thinks* those interests are not identical—is in much better position to successfully present, in proper light, the different agencies to the community.

Administration and Control

By bringing together the operating health agencies, the health center promotes knowledge by each of the others' work, elimination of duplication, consideration of health problems, and promotion of needed health work.

Administratively the health center should be under the combined guidance and control of all of the health

At the Alameda County Health Center the nucleus of an efficiently administered medical library is a definite service to the local physicians. The medical group is thereby unified and stimulated.

The scientific practice of medicine is promoted by rapidly available laboratory service for consultant and clinical staffs. Such an arrangement serves the best interests of both physician and client.

agencies. The health center must not be interested in movements towards health control by any one agency; it must seek to do good under the conditions that exist, must coordinate agencies and provide such administration as will best conserve the interest of

all of the health agencies in the field.

Summary

In short, the health center is a community health organization standing for creative health work, which aims to coordinate the efforts of all health

agencies, bring the services of all agencies to the attention of the public in such a way that they are used, "bring the community to demand, and stimulate the community to work for a higher and higher type of health service."

National Research Council and Health

BY VERNON KELLOGG, PERMANENT SECRETARY, NATIONAL RESEARCH COUNCIL, WASHINGTON, D. C.

THE National Research Council is, as its name indicates, a national although not governmental organization, interested and active in the promotion of scientific research in the United States. Indeed, its interest is even wider, for, through its affiliation with the International Research Council, organized since the war at a meeting in Brussels of accredited representatives of national scientific academies and councils of various countries, it is directly participating in certain international research activities; but its prime interest is in the encouragement and support of scientific research and the practical application of research for the benefit of the American national strength and welfare.

The Council was established under the auspices of the National Academy of Sciences during the war, to help mobilize the scientific personnel and material resources of the United States for the benefit of the government in connection with war time problems involving the need of scientific investigation. The work of the Council during the war proved so useful that President Wilson, in an Executive Order issued in May, 1918, asked that the Council become a per-

manent body for the sake of continuing its special function of encouraging and organizing American scientific effort, especially by promoting cooperation in attack on large scientific problems directly related to the national well being.

A Self-Supporting Body

The Council, as at present reorganized for peace time work, is entirely self-governing and finds its support from private, not government funds. It has been given an endowment which provides sufficiently for its current administrative expenses and is in constant receipt of other gifts devoted to the initiation, organization, and support of special research projects. Much of its special work, however, entails but little expense and is supported by its funds for general administration.

Its membership consists chiefly of accredited representatives of more than forty major national scientific societies of the country, together with a number of other members representing large public interests, especially industrial and technical. It comprises a series of divisions representing the various special fields of pure and applied science, such as

chemistry and chemical technology, the physical and mathematical sciences, geology and geography, biology and agriculture, anthropology and psychology, engineering, and medicine; and another series representing the general relations of the Council to similar foreign bodies, to government and state scientific bureaus, to the universities and colleges, etc.

Among these, it is the division of medical sciences through which the interests and activities of the Council are especially related to problems of national health, although the activities of certain other divisions touch also certain phases of the larger health problems. Each division has a chairman, resident, for the term of his office, in Washington, and is composed of a group of leading scientific men representing the special subject of the Division's interests. The present chairman of the Division of Medical Sciences is Dr. George W. McCoy, director of the hygienic laboratory of the United States Public Health Service, and the executive committee of the Division is composed of the following well-known medical authorities: Frederick P. Gay, professor of pathology, University of California; Henry A. Chris-

tian, Hersey professor of physics, Harvard University; Simon Flexner, director of the Rockefeller Institute for Medical Research; W. H. Howell, professor of physiology, Johns Hopkins University; Reid Hunt, professor of pharmacology, Harvard University; and Victor C. Vaughan, dean of the medical school, University of Michigan. Among the members of the Division are officially appointed representatives of the American Association of Anatomists, American Neurological Association, American Physiological Society, American Medical Association, American Roentgen Ray Society, American Society for Clinical Investigation, American Society for Experimental Pathology, American Society for Pharmacology and Experimental Therapeutics, American Society of Biological Chemists, American Surgical Association, American Veterinary Medical Association, Association of American Physicians, and the National Dental Association.

Ever since its organization the National Research Council has felt that the field of public health should receive its serious attention. It has made a general survey in the United States and finds numerous agencies already engaged in research in this field. Some of these agencies, such as the various bureaus of the Government, the Rockefeller Foundation, and the School of Hygiene and Public Health of Johns Hopkins University, are reasonably well supplied with resources. Some others, especially state and municipal bureaus, are usually less well equipped, but still are in position to carry on much useful research. Still others are badly lacking in equipment and competent personnel.

Aids Research Projects

As the National Research Council maintains no active operating laboratories of its own, its relation, through its Division of Medical Sciences and other divisions, to public health research, must be limited to the endeavor to initiate and organize research projects not now being undertaken but needed. It will attempt to obtain the cooperation of men and laboratories, especially suited for carrying on these projects, and to help find the necessary funds for their maintenance. If necessary, the Council, through committees of experts, will help supervise any such projects organized by it.

The Division of Medical Sciences has already set up several special committees for the planning and su-

pervising of particular projects of investigation and has lent its support to other undertakings suggested from outside sources. An excellent program for research in nephritis has been worked out. The requirements of this project in the way of funds are large, and these funds have not yet been obtained. It seems relatively easy to secure means for investigations dealing with infectious diseases, but it is much more difficult to interest foundations or private individuals in position to support research in investigations in the chronic diseases, which are nevertheless very important as a cause of invalidism and which contribute largely to swell mortality figures.

The Division is now developing a plan for certain fundamental nutritional investigations having especially in view the biochemical studies of persons suffering from various degrees of under-nutrition. This project is practically assured of financial support.

The attitude of the Council toward medical research and the advancement of medical science, is that the most significant results will be obtained from an attention to fundamental matters. Some of these matters may even not appear, at first sight, to be immediately pertinent to practical medicine. For example, the Council is administering a large gift for the establishment and maintenance of a number of research fellowships in physics and chemistry. Some of the work of these research fellows—especially the work of the fellows in chemistry—may be of great importance to fundamental medical science. The Council's Division of Biology has an important Committee on Food and Nutrition. Out of the researches initiated and supervised by this Committee will come results of much significance in public health problems.

Study the Mind and the Body

The Division of Anthropology and Psychology, in cooperation with the Division of Medical Sciences, is formulating a plan for extensive research in nystagmus and the function of the semi-circular canal. The outcome of these studies also will have fundamental value in connection with public health. The Division of Psychology is also devoting much attention to a study of tests of students having in view the possibilities of the prediction of success in special vocations. The work so far undertaken has chiefly concerned students of medicine and of engineering. If

such tests are found to give indications of value, their use may be very important in medical schools.

The Council maintains a Research Information Service which is equipped to furnish directly general information and specific data on various public health problems or to put the inquirer into immediate contacts with the best sources of the information desired. This service is provided free of charge, except in cases where unusual work is required to secure the information asked for, and the charges then are limited to the actual expense incurred in obtaining the information.

Altogether the National Research Council, through its close connection with the government bureaus and the major societies interested in medical and public health research and with the leading investigators of the country, and by reason of its efficient organization for setting up and supporting cooperative undertakings of needed investigation, is in a position to render useful service in connection with the public health problems of the Nation. And it confidently hopes to render this service.

Chicago Resolutely Faces Her Health Facts

Health Promotion Week, observed throughout the state of Illinois the week beginning April 17, was made in Chicago the occasion of a systematic survey of health conditions as the basis of intelligent health programs to be made effectual throughout the year. Sunday in the churches exemplified in Biblical texts the religious and social sanction of the earliest sanitary laws. Monday enlisted local popular interest in community "Clean-Up." On Tuesday, through the authority of local health officials, special emphasis was directed toward fly, insect, and rat extermination. Wednesday was "Better-Babies" day. "Birth Registration" day on Thursday marked an effort to locate every unregistered child in the community, and to check discrepancies of local records of the birth of children now less than one year old. Friday, "School Children's" day was observed in special health programs arranged in such a way as to inculcate health habits in the children, interest being stimulated by offering suitable prizes.

Saturday was "Medical Examination" day, and the purposes of its activities brought out the advantage of annual medical examinations to disclose organic diseases in their incipient and curable stage.

The Health Department at Flint, Michigan

Health Departments Make Spectacular Growth When Attempt is Made to Keep Pace with Local Needs

BY WILLIAM DEKLEINE, M.D., HEALTH OFFICER, FLINT, MICHIGAN

THE city of Flint, Mich., is a rapidly growing industrial town, with automobiles and accessories as the chief industry. The census figures show that the city has grown from about 38,000 to nearly 91,000 since 1910. Until three years ago the city health department was in charge of a part time health officer at a salary of approximately one thousand dollars a year. The other employees in the department were one visiting nurse, one dairy and food inspector, three sanitary officers, one plumbing inspector, and one clerk. The annual appropriation in the city budget for the department was about \$15,000.

Scope of Work Broadens

In May, 1917, a full time health officer was appointed and placed in charge of the work under the supervision of the former Board of Health consisting of two members. That same year money was appropriated for a bacteriological laboratory, but none for expansion along other lines. The following year, 1918, the budget was increased to about \$25,000; in 1919, to about \$45,000; and in 1920, to about \$80,000. The department has grown and expanded a little each year, till at the present time it has thirty-one full time employees, of whom three are physicians, five dentists, eleven visiting nurses, two bac-

teriologists, three dairy and food inspectors, three sanitary officers, two plumbing inspectors, one stenographer, and one clerk. Besides this number the Board of Education of the city employs eight school nurses. Three years ago the department was located in one room in the city hall; at present it is occupying an entire building known as the "Health Center" and it is one of the busiest municipal organizations in the city.

The scope of the work has broadened considerably in the last two years. The department is now organized along the following lines: A Division of Communicable Diseases; Dairy and Food; Laboratory; Visiting Nurses; Vital Statistics; Public Sanitation; Plumbing Inspection; and a Clinical Division.

The clinical division includes the following: Dental clinics principally for school children with five full time dentists in charge; medical clinics for school children with one full time physician in charge, designated as the school physician; a general clinic for people in poor financial circumstances; and also a clinic for drug addicts with one full time physician in charge, designated as the city physician.

The dental clinics are open all day from 8 a. m. until 5 p. m. The school physician and city physician have cer-

tain office hours every day during which time patients who belong in the above named groups can come for consultation, the hours being so arranged that one or the other physician is here during the entire day.

The other clinics are the tuberculosis clinic; eye; ear, nose, and throat; prenatal; orthopedic; venereal; gynecological; and a nervous and mental disease clinic. Each one of these clinics is conducted by one of the local practising physicians who specializes in the particular branch of which he has charge. During the summer months four additional infant welfare clinics are conducted in school buildings in different parts of the city in charge of the school physician and one or two of the local physicians.

Clinical Work Unique

No attempt will be made to describe the work of all the divisions of this department, but this paper will be limited to a description of the activities of the clinical division. The work in the other divisions is along the usual lines, perhaps not differing from that of other health departments in cities of this size. The work in the clinical division is different, perhaps unique, because it is organized for the purpose principally of correcting physical defects in school children. We emphasize children be-

Three years ago the Health Department of Flint, Mich., occupied one room in the city hall. It now occupies an eighteen-room building and is now one of the busiest municipal organizations in the city.

Nutrition clinics looking toward giving the babies a right start, and affording the necessary guide and supervision of the mothers, constitute an important service at the Health Center of Flint, Mich.

Chief emphasis is placed on the work with the children, as the best opportunity for preventive medicine.

This room is devoted to the treatment of venereal disease. Day and evening clinics are held.

cause we believe that whatever work is done for them in a corrective way is more far-reaching in its final results than similar work among adults; although we aim also to do considerable corrective work among adults who would otherwise be neglected. We believe that the biggest opportunity in preventive medicine lies in this field, especially in the elimination of focal infections wherever possible; because this work has been neglected.

The health department is housed in a building which was formerly a large residence. It is located in the center of the town, one block from the main street. The lower floor is used for the department administration and for all the divisions except the laboratory and the clinical division. The laboratory is located in the hospital which is a municipal institution, and serves both the hospital and the health department.

The clinical division occupies the entire second floor of the building. This floor has a waiting room, two dental rooms with three chairs, two clinic rooms used by the physicians for examination rooms; on treatment room for venereal diseases; a sterilizing room, and a record room and nurses' office. The clinical division is placed under the general direction of the school physician, since most of the work has to do with school children.

The common council has recently appropriated funds for a substantial

addition to the rear of this building. The work is about completed.* This addition will have a well equipped operating room, sterilizing room and a hospital ward room with space for seven beds. It will also have space for the erection of x-ray equipment, four additional clinic rooms, and a treatment room for venereal diseases. This addition will also make space available in the building for a reading room for physicians. It is planned to organize a medical library in connection with this reading room and it is hoped that in a few years a well selected library will be collected for use by physicians, dentists, and nurses.

The operating room will be used principally for nose and throat surgery, dental extractions under anesthetics, orthopedic surgery, and emergency surgery. This room will also be made available to physicians in private practice. It will give them a place to do such surgery as is frequently done in their offices, under better aseptic conditions and with competent assistants, without compelling the patient to go to the hospital. The operations will be scheduled if possible in the morning and the patients removed to their home in the afternoon. A small charge will be made for the use of this room.

During the course of the year every

*The new addition has been completed since this paper was prepared. The operating room and additional examination and treatment rooms are now in use.

child in the school grades is examined by the school physician and by one of the dentists. Notes are sent to parents as to the conditions found and through a system of "follow-up" work the parents are interviewed by the school nurses. The financial circumstances of the parents are also investigated at the same time and every effort is made to induce them to have the necessary corrective work done either through the private physician or dentist or through the clinic.

In point of numbers the largest service is rendered in this clinical division, through the dental clinic, and it is necessary that this is so because by far the greatest number of defects in children are found in the teeth. While from 20 to 30 per cent of school children in the grades have diseased tonsils and adenoids and about 10 to 20 per cent defective vision, 85 to 95 per cent have defective teeth in some form or other. It will require a far greater number of dentists to correct teeth defects than physicians to correct other physical defects. It often requires several hours to treat the teeth properly and a comparatively much shorter time to remove tonsils and adenoids, or to refract the eyes, etc. It is also much easier to get the consent of parents for dental work than to have other operative work done. Therefore, there is a much greater need and call for dentists than physicians to do corrective work

among school children. With three full time dentists on the staff last year we were able to give free dental care to about twenty-five hundred school children. The work on the dental clinic is done almost entirely by appointment, similar to the handling of work in a private office. The children are given appointments by the school nurses and it is their duty to see that their appointments are faithfully kept. In this way the offices are never over-crowded with applicants nor idle for lack of them. Not all the dental work is done at the central clinic. Some branches have been established in the outskirts of the city.

The teaching of dental hygiene alone is not going to have a very large influence upon the health of the children unless we also correct their dental defects and all mouth defects.

Our department is now organized to give free dental care in this coming school year to about 35 per cent of the school children in the grades. The dental society of this county is in hearty accord with this work as is evidenced by a resolution recently passed by the society endorsing the work of the Health Department in establishing free dental clinics.

Occasionally I hear the opinion expressed that this school work will interfere with the work of dentists in private practice. Dentists in this city are doing more work for school children at the present time than they have ever done before. The records of the school nurses show a marked increase in this respect. They are also becoming more interested in this branch of dentistry. One dentist in our city is specializing in work for

However, I do not want to leave the impression that we do other corrective work free for all school children. We try to direct them to their physician or to the clinic if such work is necessary.

As stated above, we are organized to give every child in the grades a physical examination during the course of the school year. This examination includes the eye, ear, nose and throat, teeth, the chest, bone deformities, skin diseases, etc. The examinations are made at the schools. The children are taken out of the class room just long enough to give them a routine examination. Any of the children who are found to be apparently subnormal and who in the opinion of the physician require a more careful examination are referred to the clinic at the Health Center. One of the parents usually accompanies them. In this way we are able to give them a more careful and complete examination, and give the parents better directions as to the treatment.

I do not want to convey the idea that all our clinics are conducted for the benefit of school children. The tuberculosis, venereal disease, prenatal, gynecological, nervous and mental diseases and drug addict clinics are necessarily almost entirely for adults. These are conducted by local physicians under the general supervision of our city physician. The routine work such as writing of histories, filing of records, preparation of the patients, etc., is done by the nurses in charge. In this way we are assured of more regularity and promptness in carrying out all the necessary details. We aim to conduct a well regulated series of clinics.

Clinic Schedule

Baby Clinic

Tuesday—3:00 p. m.

Thursday—10:00 a. m.

Venereal Clinic

Women:

Tuesday and Friday—8:30-9:00 a. m.

Tuesday evening—6:30-7:00 p. m.

Men:

Monday and Thursday—8:30-9:00 a. m.

Management favoring the normal development of the child is the special function of the Child feeding clinic. Medical and nursing care is not half so important as the provision of a system which insures for all children in the community uniform and adequate nutrition.

Hundreds of our school children have badly infected mouths resulting from dental caries and there is no opportunity offered anywhere to have this corrected. The average dentist in private practice is not interested in doing preventive work for children, either because he does not realize the importance of it or because he cannot see as big financial returns from that class of work as from adults. For that reason if we ever hope to remedy these conditions in children it is up to the community to do so.

children and he is kept busy all the time. If we give free dental care to our children and can preserve their teeth until adult life, we have made them ardent advocates for proper dental care. Free dental care among school children increases the work for private dentists.

This applies equally well to physical care along other lines. I can think of no better way in which to increase the work of the private physician than by doing free medical work among our school children.

An orthopedic clinic is one of the most important adjuncts to the "Health Center," making it possible to carry out the long and arduous treatment necessary.

The personnel of the Health Department of Flint, Mich., includes thirty-one full-time workers, besides which number the Board of Education employs eight school nurses.

Friday evening—6:30-7:30 p. m.
General Clinic
Daily—9:00-10:00 a. m. and 2:00-4:00 p. m.
Clinic for School Children
Daily—3:30-5.00 p. m.
The schedule above gives the time when these various clinics are held.

They are so arranged that they will not interfere with each other or with any of the other regular work of the clinical division. Two nurses or frequently three are in attendance all the time. The present average attendance is about eighteen hundred visits

a month. This does not include the work done outside in the school and infant welfare clinics. These are visits in our clinical division at the Health Center which is strictly a civic enterprise. It is a popular effort to achieve a complete service.

Compensation for Industrial Disease

EIGHT jurisdictions — California, Connecticut, Hawaii, Massachusetts, New York, North Dakota, Wisconsin and the Federal Government—provide compensation for occupational diseases of the forty-six having compensation jurisdiction, according to a study published by Carl Hoopstadt in the February issue of the *Monthly Labor Review*. In Massachusetts, North Dakota, and the United States, the inclusion was brought about by the commissions and courts and in the other states by statutory enactment. The reports and investigations show that the maximum cost of occupational diseases, if included in the workmen's compensation acts, would not be greater than 2 per cent of the aggregate cost of industrial accidents and would probably be less. Under the Federal Compensation Act for the year 1919 there were 19,354 injuries, with 299 cases of disease, that is, 1.5 per cent. In California for the same year the total injuries were 58,577, with 670 injuries from poisonous and corrosive substances, or 1.1 per cent of all injuries, and 455 cases of industrial disease, or 0.8 per cent of all injuries. In Massachusetts for the period 1915-1919, there were 1,738 cases of fatal injuries, 51, or 2.9 per

cent, occupational diseases; 290,920 non-fatal injuries, with 3,788, or 1.3 per cent, occupational diseases.

The term "occupational disease" may be classified by cause and nature of injury: Diseases due to the gradual absorption of poisons (lead poisoning); diseases in which the poison or germ enters the system through a break in the skin (anthrax); skin affections from acids or other irritants (eczema, dermatitis); diseases due to fumes or dusts entering the system through respiratory organs (tuberculosis, gas poisoning); diseases due to vibrations or constant use of particular members (neuritis, telegrapher's cramp, housemaid's knee); and miscellaneous diseases (caisson disease, miner's nystagmus). In addition to these, compensation is usually granted for typhoid fever, erysipelas, pneumonia, and ivy poisoning, which arise from and are proximately caused by employment. To be compensable, they must be directly traceable to the employment. Diseases arising from, accelerated or developed by an accident, are compensated, not for the disease *per se*, but the results of the accident. Had the accident not occurred, the disease would presumably not have developed;

hence the disability is directly attributable to the accident.

In some states, where the compensation laws do not cover occupational diseases, the courts and commissions have awarded for most of the diseases enumerated; if the disease resulted in violence to the physical structure of the body, i. e., if traumata a production of a lesion; if injury accrued unexpectedly or not in the usual course of events; if the injury can be traced to a definite time and place in the employment; and if the injury was not due to a known and inherent risk of the occupation; or, even if inherent in the occupation, if the employer had neglected reasonable safeguards which presumably would have prevented the injury.

Health Certificates Before Marriage

A bill has been introduced into the Michigan state legislature requiring all persons applying for marriage licenses to present a licensed physician's report of the physical condition of each applicant. Persons afflicted with venereal diseases, epilepsy, or "open" tuberculosis are barred from contracting marriage.

Universal Physical Education is Essential

Health a By-Product of Physical Education.
Universal Training Safeguards the Future.

By HONORABLE ARTHUR CAPPER, UNITED STATES SENATOR FROM KANSAS, Washington, D. C.

OUR national pride received a severe jolt with the publication of the draft statistics showing more than 35 per cent of the young men examined physically disqualified from full military activity. On the heels of this announcement came the publication of the equally startling results of various surveys relating to the health conditions of school children. It was alleged that not more than 25 per cent of the school children of the nation could be regarded as fully fit, physically.

These revelations have roused a widespread interest and study of the problem of how best to set in motion the processes which will successfully combat this unsatisfactory condition. While it is recognized that many of the activities in peace time do not require the degree of physical perfection needed for effective military service, yet we cannot deny that the conditions revealed indicate a material sapping of the energies of the nation for industrial, agricultural, and professional activities in peace time.

Compulsory Military Training

The advocates of a continuous program of compulsory military training for all young men between the ages of eighteen and twenty-one have argued that in addition to strengthening the nation for national defense, such a program would facilitate the effort to overcome the physical deficiencies revealed by the draft. I have expressed myself openly as being opposed to the proposal for compulsory peace time military training. I regard this as a matter to be considered mainly from the standpoint of providing the adequate defense of the nation. I am against such a program because I regard it as unnecessary in providing for the adequate defense of the nation and because of the tremendous expense involved.

If we cannot justify compulsory peace time military training as a necessity for national defense, we certainly cannot justify this plan—involving an expenditure of at least five hundred million dollars—as a means for promoting the physical fitness of the nation. In the first place, it

would apply only to the young men, and I am thoroughly convinced that whatever we may do in providing better opportunities for health and physical efficiency should be extended also to our young women. Furthermore, it is true that the basis for ill health and inadequate physical development, when they appear in later life, has usually been established previous to the eighteenth year. No extended argument is necessary to prove that we cannot, in a period of six months' military training at the age of nineteen, overcome the results of ignorance and neglect during the earlier years.

Educate the Young

I would not advocate universal physical education as a substitute for compulsory military training in providing for national defense. However, I am convinced that the most hopeful method of improving the health and physical efficiency of the nation is not to be found in the establishment of compulsory military training at the age of nineteen. Neither do I believe that we can hope for much progress in mere efforts to discover and correct the physical defects now existing among children or adults. We must, rather, extend to all the young children adequate training in the practice of healthful habits. We must teach them what and how to eat and the other fundamentals of health, such as the proper amount and conditions of sleep and proper clothing. Furthermore, we must stimulate and guide our children in those physical activities which incidentally yield health and normal physical development. I do not mean by this that we must try to make athletes and gymnasts out of all our children. I do mean, however, that we must carry on the proper supervision of those activities which develop alertness, poise, good posture, and the spirit of team play.

I regard health as a natural by-product of physical education. If space would permit, I might elaborate upon the significance of physical education in the promotion of mental efficiency and sound moral qualities.

We have passed the day when we regard time and money as wasted when spent in guidance of the play of children. We have learned to realize that by promoting happiness and the joyful optimistic outlook upon life we are also promoting productive efficiency. After all, the condition of the spirit determines in large degree the effectiveness with which we work.

Chance for Each Youngster

We do not need to establish special schools and camps throughout the Nation in order to extend the opportunity of adequate physical education to all the children. We already have facilities for education—school houses and teachers covering the entire land. Through these facilities, about one-tenth of the children are already receiving more or less adequate physical education. The other nine-tenths can be reached by the establishment of physical education as a part of the training program in every school of the Nation. I am firmly convinced that this is a matter which should be primarily in the hands of our educators. Already there is a growing appreciation of the fact that no matter what we may do to train our children in reading, writing, arithmetic, craftsmanship, and agriculture, we are failing to give them an adequate start in life unless we also provide adequate physical education. Without a strong and efficient body, the mental training will be of little value to our youth.

Federal and State Cooperation

Now if physical education is to be made a fundamental part of education—and I feel sure that this is the only wise method—the major responsibility must rest with the states and local communities. The Federal Government cannot and should not interfere with local and state control of education. It is a bit discouraging, however, to note that in spite of the progress of physical education during the past twenty years, only one-tenth of our children are receiving this training and many of the programs now operating are lamentably inadequate. It is also true that the an-

nual appropriations of all the state legislatures for physical education total less than five hundred thousand dollars.

The Federal Government can, however, through entirely appropriate action, stimulate the more rapid extension of this important training. I believe, furthermore, that without any improper intrusion into the affairs of the states, the Federal Government can help promote economy and effectiveness in the extension of physical education. We must provide for the universal establishment of physical education in our own American way. We do not wish to follow the method of Japan, where physical education was established twenty years ago by imperial edict as part of the program of every school. We do not wish to follow in the footsteps of France, where only recently the national legislature enacted a law requiring that physical education be established for all boys and girls up to the age of sixteen. We shall wish to preserve local autonomy in the determination and administration of programs of physical education, but we shall also find it necessary to add the stimulus of helpful Federal cooperation with the states if we are to secure the establishment of universal physical education within the next twenty years. I do not believe that we shall be less effective than are the poverty stricken nations of Europe in extending this fundamental training to their children, but we shall do it in our own way.

Physical Education Measure

In the preparation of the National Bill for Physical Education, I have cooperated with Representative Simon D. Fess, who, before entering the United States Congress, was for many years a prominent educator. Advice has been received from many competent physical education authorities. The Bill, which is number 22 in the House and number 416 in the Senate, proposes that the Federal Government shall cooperate with the states in the expense of training and employing teachers of physical education. This cooperation will be extended to those states attaining certain minimum standards specifically described in the Act. These standards are moderate and only sufficient to insure that the Federal appropriations will not be wasted. No arbitrary authority is given to any Federal official or board to impose requirements beyond those specifically described in the Act. The amount available for each state is based upon

the number of children between the ages of six and eighteen. No state can receive more than the amount already appropriated by state and local authorities for the same purposes. In order to continue receiving Federal aid, the states must within five years provide the opportunity of physical education for all persons between the ages of six and eighteen. The total Federal appropriation to be available for distribution is ten million dollars. It is probable that during the first year only a part of this appropriation would be expended.

The Bill provides for the establishment of a Division of Physical Education in the Bureau of Education, which shall be equipped to administer the Act and to cooperate with those states desiring assistance for increasing the quantity and improving the quality of their physical education programs. The United States Public Health Service is authorized to cooperate with the Bureau of Education and with the states in giving technical advice relating to health supervision. I wish to emphasize that the administration of the Act is to be assigned to the Bureau of Education. I believe it is a sound policy to place the responsibility of this program in the hands of the educators and that the relationship of the health authorities should be advisory. I wish further to emphasize that we have included in the Bill a provision making clear that there shall be no discrimination between the various recognized schools of medicine and that nothing in the Act shall be interpreted as requiring minors to receive medical examination or treatment against the expressed wish of their parents or guardians.

What is Real Economy

The necessity for extreme economy in Federal appropriations is well understood. I regard the physical education bill as an economy measure. Real economy does not always mean simply refraining from expenditures. Wise and conservative investment for the realization of assured profits is one of the wisest forms of economy. It has been conservatively estimated by the United States Commissioner of Education that last year there was a loss of approximately one hundred million dollars in the public schools because of absence of enrolled children due to ill health. The young people in industry under the age of nineteen—who would be affected by the legislation—lost through ill health last year \$71,250,000. These are only two of the readily calculable bills

paid by the nation as the price of ill health and physical deficiency. If we can reduce these amounts alone by as much as 10 per cent, we shall have saved more than the entire cost involved in this legislation. While we are spending hundreds of millions for battleships, I cannot but regard the proposed expenditure of ten million dollars for promoting the physical fitness of our youth as a wise and economical investment.

Graduated Exercises Prescribed for Cardiacs

Surgeon B. W. Carr of the United States Public Health Service, writes in the *American Journal of Electrotherapeutics and Radiology*, March, 1921, on "Graduated Exercises in Cases of Functional Heart Disturbance," basing his conclusions largely on observations of young men in the army hospitals. Interference with normal action of the myocardium in performing its various functions of conductivity, contractility, tonicity, etc., may cause functional heart disturbances so that it is not surprising that under the stress of army life a great many men develop cardiac symptoms sufficiently grave for hospitalization.

There are five grades of exercises used at Walter Reed: Grade I, passive and resistive exercises; Grade II, Active exercises, in lying and standing position; Grade III, Active exercises with coordination; Grade IV, To speed with coordination; Grade V, Walking and slow running, graded. In the lower grades, special efforts are made to induce muscular relaxation and lowering of nervous tension. Rest periods with complete relaxation are frequent. Grades II and III are increasingly vigorous. The type of exercises differed in various hospitals. Grade I exercises used at Lakewood were too strenuous for some of the cases at Walter Reed.

The value of graduated exercises in functional heart disturbances must be conceded, but to obtain good results, treatment must be systematic and under complete supervision. Each case is considered individually and advance in grade only as the condition indicates. Indiscretion of diet or exercise during the rest of the day may nullify the benefits of the treatment. Rest is of the greatest importance. The tendency noted towards an increase in the number of heart defects is best counteracted by a concerted effort to find and segregate the chronic cardiac sufferers and to prevent by a precise régime the progressive damage that results from all advised exertion.

Locking the Barn Door in Health Legislation

By COURTENAY DINWIDDIE, EXECUTIVE SECRETARY, NATIONAL CHILD HEALTH COUNCIL, WASHINGTON, D. C.

IN EVERY branch of human welfare activity the child has the greatest appeal. This is as it should be, for in the child we have the opportunity to influence the thought, the habits, the health, and the happiness of the next generation. Therefore, it is peculiarly unfortunate if, in planning or working for children, we think chiefly in terms of the sick, the crippled, and the sub-normal. For ten years or more there has been a trend in the other direction, toward planning and working for the normal child and the one that is well, with a view to keeping him so. This tendency was at first very slow but is gradually increasing.

"Child Welfare" legislation, however, still deals very largely and in some cases exclusively with the dependent, defective or delinquent child. It often takes comparatively little account of health or of the necessity of working for those conditions and of promoting those habits that shall make it possible for the average child to be sturdy, independent, and happy through the combination of right thinking and right living.

It was for this reason that the National Child Labor Committee, a member of the National Child Health Council, pointed out to the latter the urgent need for information as to desirable health provisions for state laws relating to children. This was in December and a number of State Children's Code Commissions were preparing legislative recommendations, some for use in January. Therefore it was necessary to organize quickly an authoritative committee on this subject. The committee appointed consisted of Courtenay Dinwiddie, executive secretary of the National Child Health Council, elected chairman; James A. Tobey, assistant director, Health Service Department of the American Red Cross, elected secretary; Richard A. Bolt, general director of the American Child Hygiene Association; E. Dana Caulkins, manager, National Physical Education Service; Taliaferro Clark, M.D., surgeon, United States Public Health Service; Edward N. Clopper, assistant secretary, National Child Labor Committee; Anna E. Rude, M.D., director, Division of Hygiene, United States Children's Bureau; and Willard S. Small, Ph.D., United States Bureau of Education.

This committee reported on January 7, 1921, an outline of suggested health provisions for state laws relating to children. This outline emphasizes the importance of thoroughgoing consideration of health, in drafting child welfare legislation. It then proceeds, beginning with the prenatal period, to take up those problems occurring through the different age groups, which need legislative attention.

Restrictions Removed

The report first warns those who are drafting legislation not to forget that the simple inclusion of a certain measure in legislation may not end the matter. It stresses the importance of the removal of all restrictive legislation, such as limitations as to tax rates and levies, and the need for positive authority and facilities for promoting and for undertaking the various measures suggested.

Examples of things which should be promoted by legislation for the protection of the child during the prenatal period, are facilities for the education of expectant mothers, for the establishment of prenatal health centers and clinics, for the protection of expectant mothers in industry, and for the health supervision of mothers.

For the protection of the child at the time of birth, regulations requiring the licensing of midwives, proper educational requirements and adequate health supervision for any training that may be given them, are recommended.

Control of ophthalmia neonatorum, sound measures for prompt reporting of births and supervision of maternity homes are among other subjects dealt with.

For the infant and pre-school child it is recommended that legislative restrictions be removed and definite legislative authority be granted, so that adequate facilities for the protection and promotion of health can be provided by state and local authorities. This is followed by provision for the control of milk and milk products.

Legislative provision is recommended for the training and instruction of all children of school age for the purpose of developing health habits through supervised physical activities, free play, and practical instruction in hygiene, nutrition and sanitation. The Committee empha-

sizes here the need of scope for the development of initiative, spontaneity, and responsibility on the part of the child. Attention is called to the need of providing funds and other means for the promotion of such work by state authorities.

Periodic physical examination and health supervision of school children are next taken up in the report, followed by references to health classes for special groups and recommendations for securing sanitation of school houses and their environment.

The need for physical supervision and health education of children of school age who may be in industry is emphasized.

The Committee calls especial attention to the importance of a bureau of child hygiene in each state, in which should be vested the administration of all legislative provisions affecting the health of children, except those which properly pertain to other state agencies. The necessity of coordinating the work of this bureau with others is emphasized.

Reference is then made to the need for seeing that public and private institutions, agencies, courts and boarding homes, caring for dependent, defective or delinquent children, shall be required by law to have adequate health supervision over their work and wards, subject to the regulations of the health authorities.

It is similarly urged that measures dealing with the appropriation and expenditure of funds for material relief in connection with child or maternity care should specifically make provision for adequate care of health.

The Committee does not attempt to draft specific legislation or even to indicate what the details of such legislation should be. However, it does cite nine reports and pamphlets on model laws and allied subjects which furnish the basis for drafting such legislation relating to the health of children.

Copies of this report are available at the office of the National Child Health Council, Washington, D. C., for those interested in child health and welfare legislation.

A model hospital for children is to be erected and financed by the American Red Cross at St. Mihiel in memory of the first great American effort of the war.

The Anatomy of Feet and Their Full Efficiency

The Feet are Entitled to Careful Study and
Plenty of Exercise to Keep Them Conditioned

By MARTHA M. BACON, M.D., ASSOCIATE PROFESSOR OF PHYSICAL EDUCATION, LECTURER ON HYGIENE, AND MEDICAL ADVISER TO WOMEN, UNIVERSITY OF KANSAS, LAWRENCE, KANSAS.

RACES as well as men are distinguished by the character, and usefulness of their feet. The Englishman has feet which are fleshy and short, but lacking in strength and character. The Scotch foot is high and thick, showing a great power with the ability to stand long marches and other tests of endurance. The French have esthetic feet—long, narrow, well proportioned—and they are considered very beautiful. The Russian has a peculiar foot, with the skin between the toes usually webbed to the first joint. The Mexican foot is short and strong with a noticeable distance between the second and great toe. The feet of the Chinese lady were about as beautiful as a horse's hoof, which they resembled after the process of beautifying was completed. They bound the feet of the girl when she was about seven years old. The great toe was left untouched, but the other toes were turned under the foot and bound, loosely at first, then the bandages were tightened until the growing nails would often pierce the quivering flesh. The American foot is well formed but inclined to be short for the height of the individual and, like that of the Chinese, has been the victim of barbarous treatment.

Practically all foot troubles other than those of congenital origin, are due to ill fitting and improper shoes and the vanity of the American woman, who has never stopped to study the anatomy, physiology, and hygiene of the foot, and does not real-

ize the importance which they bear to health, happiness and success in life.

The normal human foot is a graceful and beautiful thing, although it is next to impossible to find a normal foot when high heels and pointed shoes have been worn, and so we must turn to art and sculpture for our models.

The remarkable thing is, however, that with all the deformity and distortion inflicted by our shoes, the baby is born with normal feet and the dimpled bit of humanity, with the soft, pink and white toes, is a thing of beauty for the simple reason that it has never worn shoes and it might well remain so if mothers would study the anatomical structure and physiology of exercise in relation to the feet; giving this matter the care and attention which it deserves as one of the important parts of the body if not the most vital to the comfort, success, and happiness of the individual.

Defects Nearly Universal

It seems strange that so little has been accomplished in caring for the feet, when we realize that about 90 per cent of the human race suffers from some defect or deformity of the feet which might have been prevented.

At last we have awakened to the fact that hundreds of ailments which have been attributed to the teeth, tonsils, eye-strain and various other causes are in reality caused by wearing shoes which produce corns, calluses, bunions, and which distort the

bones of the feet then press upon sensitive nerves and interfere with the proper circulation.

Many of the nervous troubles, such as headache, chronic pelvic disorders, and rheumatism, are directly due to the effects of ill-fitting shoes. The high heels throw the body out of alignment, causing a displacement of the stomach, bowels and pelvic organs which interfere with their normal healthy action and produce pain and disease.

A deformed child, with longing wistful eyes, watching his fellows at play, fills us with pity and we exclaim, "How terrible to be deformed!" Yet to every one who is made lame by accident or birth, there are thousands who are voluntary cripples or partially lame by wearing ill fitting or badly constructed shoes.

When we realize the value of good feet we will give them more care and learn something of their physical makeup. The child will be taught how to take care of his feet, just as he is now taught how to use the tooth brush and to manicure his nails. The time is ripe for a campaign for "better feet" and "foot hygiene." No one subject is more important, has more to do with public health or the welfare of the individual, and it seems strange that so little attention has been given to it.

The work of the army in the great World War has done much to improve conditions by causing shoes to be constructed on better lines and teaching men how to care for their feet.

Arrow points to seat of pain. Anterior arch beginning to fall.

Second degree. The great toe is pushed inward by narrow shoes.

First degree cavus. Note the bad callus on base of left foot.

This foot belongs to Type I. Shoes have rotated the foot.

Second degree flat foot. The foot has been crushed into too narrow shoes.

Type I. Normal foot of Claire Newton. The toes are very straight and flexible.

Third degree cavus or contracted arch, a frequent defect in the series reported.

Type III, long, narrow foot. Arrow on right shows the location of the pain.

Much has been written on the subject, but there is still a great deal to say, as the masses of the people know very little of the hygiene of the foot and are not putting into use the knowledge which they do possess.

The feet of the ancient Egyptian are said to have been beautiful because they encased them in sandals which allowed freedom of motion. When he entered the house his sandals were removed and his feet were bathed. The sandals gave adequate protection in the dry warm Egyptian climate, while permitting free action and giving light and air which are necessary to the health and development of the feet.

The early Roman shoes were called buskins. The sole was similar to that of the sandal, but the top laced up the leg and allowed freedom, instead of cramping the toes and forcing them on top of each other as our shoes do now.

The Germans early recognized the importance of good pedals and inspected the feet of their soldiers twice a week in the barracks and more frequently while on field maneuvers. The Germans also appreciated the fact that the hose had much to do with the comfort of the feet and provided their men with strips of cloth soaked in tallow, which they bound about the feet in such a manner as to avoid all wrinkles. In this way they prevented blisters.

Value of Correct Dressing

America proved the value of correct dressing of the feet and has provided for her soldiers good shoes made on correct anatomic lines, free from wrinkles, and very smooth on the inside. The sole is moderately thick and has a broad, low heel. The shoe reaches a little above the ankle and is provided with eyelets instead of hooks for fastening, as more comfortable to wear and fitting the out-

lines of the foot better. It weighs only two pounds, while the German shoes weigh twice as much. The shoes of the American soldier are neat, comfortable and easy to put on and remove.

The human foot is an elastic arch composed of three divisions—the tarsus, metatarsus, and phalanges—comprising in all twenty-six bones, which are bound together by muscles and tendons, with an abundant supply of blood vessels and nerves. This forms the tripod upon which the weight of the body falls. The elasticity of the arch prevents the jarring of the frame during movements, and gives to the step the spring of youth. The foot consists of two arches—the longitudinal, which is long and sloping and extends from the heel to the ball of the foot; and the second or transverse arch, which is short and high, running crosswise of the foot from the outer edge of the sole where it touches the ground to the instep. The weight of the body is balanced on these arches.

Defects of Two Classes

We are dependent on the muscles of the foot for locomotion and for that reason they are entitled to receive careful study with plenty of exercise to keep them in good condition. Nothing is better than walking and climbing to keep the feet in good physical health.

There are many causes of deformities of the feet but they fall under two general classes: congenital and acquired. The acquired deformities are due to some disarrangement of the bones of the feet and the treatment comes under methods of prevention. The measures for correction should begin in early childhood, when the bones are soft and the centers of ossification are just making their appearance. The foot then is mostly cartilage and the least amount of pres-

sure will cause a distortion, followed by permanent deformity, and, if the pressure is continued the result will be a contracted foot. The baby's shoes and stockings should both receive careful attention. Going barefoot not only develops the muscles of the foot, without making it larger than nature intends, but it gives flexibility to the toes and an elasticity to the step which can only come in a normal foot whose bones are in the right place and with arches that are built to support the weight without fatigue. When the muscles which hold the arches in position lose their tone the bones sink, resulting in the condition known as flat feet. The bones press upon sensitive nerves, making walking difficult, painful, and often impossible.

The normal foot is straight and broad at the ball, with a space between the toes, which are straight and flexible. The width of the arch is about one-tenth the distance from the base of the heel to the end of the second toe. The correct position in walking is with the feet pointed straight ahead. The inner border of the foot should not touch the floor. The heel, ball and toes support the weight on the ground.

The author has made more than five hundred examinations of the feet of girls at the University of Kansas and in the whole series has found but one girl having feet which could be called normal. The possessor of these unusual pedals is a young medical student who was born in China, the land of tortured feet. Her father and mother were American missionaries and Claire Newton spent her childhood going barefoot and playing in the sand with her toes trying to imitate the coolies in the exercise. Claire thought this was sport and did not know she was developing perfect feet, something rare and almost unknown. Her foot is broad at the ball and the

toes are very flexible, almost as much so as her fingers. While the foot is broad, it looks dainty and very attractive, and may have something to do with the lovely disposition and character of the possessor, who also has a mind that corresponds.

An examination of her sister's feet, revealed the same type of foot, but one arch was cavus and that of the other foot was slightly flat. While she, too, was born in China, her parents were in America when she was between the ages of six and twelve, and during this period probably she wore shoes which caused the abnormal condition.

Four Types of Feet

In the series of prints made at the University, the feet may be considered as belonging to four types: (1) The first is represented by Claire Newton's feet (Fig. 6), with toes flaring and the ball of the foot broad and straight across. (2) in the second type the toes follow a graceful curve. (3) The third type is a long narrow foot; while the fourth was (4) short and dumpy. The last two types were rather rare in our series.

In the examinations of 338 girls, there were found 106 cases of flat feet, varying from that of the first degree to a complete breaking down of the arch, or the third degree, flat foot. There were 82 cases of cavus or high arch, which included the contracted arches. We found 87 cases which we have classified as "mixed," this group exhibiting a combination of flat foot and cavus, varying in degree. Sometimes the right foot was flat and the left cavus, while in another individual the condition would be reversed; or one foot might have a normal arch, while the other was either cavus or flat, and varying in degree. There were 87 cases

which could only be classed as sub-normals, the arch itself would be nearly normal with toes distorted, or perhaps one foot rotated either inward or outward; and, again, it might be corns, calluses or bunions deforming the foot.

The feet of the negro girls were almost invariably flat. We have been repeatedly told that the North American Indian has beautiful feet and we would be prepared to believe this is true if we could find him in his native environment, wearing his moccasins. The recent examinations made of thirty-five Indian girls at the Haskell Institute is most convincing that the American shoe is ruining the American woman's foot, and the most prolific cause of flat foot, cavus, contracted foot, corns, calluses, bunions, and associated with about all the ills of human kind.

There were three Indian girls whose feet might be classed as normal, and one may be called perfect, this last being the feet (Fig. 10) of Beulah Clayazzie, age 20, five feet five inches tall, and weighing 149 pounds. She is a full blood Navajo and has worn moccasins all her life until she recently came to the Indian school which the Government supports. This print is different from any which has been made in that the second joints of the second and third toes show in the print. There was one case of the mixed variety of feet, the left one being a contracted foot and the right one cavus of the second degree. All the others had flat feet, varying from that of a beginning of the anterior arch to fall, to that of the third degree flat foot. Nearly all of the girls complained of pain and there seems no question as to the cause of the trouble.

Aside from the deformity of the arches, their feet were nearly all very

soft, the skin was of a beautiful texture, and they were comparatively free from corns, bunions and twisted toes—which seems to prove that the incorrect shoes destroy symmetry of the bony structure first.

From a casual glance the plump little feet of the Indian maid appeared more beautiful than those of the college girl, but examination revealed the fact that the feet unaccustomed to confinement suffered greater damage when crushed into shoes with high heels and pointed toes than did the feet of those trained to wear the unhygienic footwear from early childhood.

London Conference on Child Welfare

An English speaking conference on infant welfare will be held in London, July 5, 6, and 7, under the patronage of the Minister of Health. The main subjects to be discussed are: residential provision for mothers and babies; environment as a factor in racial health; and the supply of milk, its physiologic and economic aspects. Every evening during the conference lectures will be given to infant welfare workers relating to the ideal maternity and child welfare center, the psychology of the mother and her child, common infections in mother and child, and other pertinent topics.

Health Work by Labor Gangs

Dr. T. F. Abercrombie, health officer of Georgia, has suggested that convicts and other gangs working on the roads be required to fill up pits, clean ditches, place culverts properly, and attend to other important details, which would deprive the mosquito and various other insects of many breeding places and incidentally reduce the malaria hazard of the state.

Mixed class. The left foot shows cavus and the right flat foot, first degree.

Normal feet of a full blood Navajo Indian girl. Toes are flexible and straight.

Normal foot with outlines of dress slipper and ground gripper shoe.

Third degree flat foot. The dark shadows on inner lines indicate a recent condition.

Periodic Physical Examination—A National Need

Fifty Per Cent of Our Working Population Are in Need of Important Medical or Physical Attention

BY EUGENE LYMAN FISK, M.D., MEDICAL DIRECTOR, LIFE EXTENSION INSTITUTE, NEW YORK CITY

IS THERE a national need for periodic physical overhauling of the bodies and lives of our citizens? Not so many years ago few people would have answered this question in the affirmative. Even now the extent to which such a procedure is a national need is appreciated by a comparatively small number of people.

The underlying common sense of the principle that it pays to inspect the human body periodically and apply scientific knowledge in correcting defects or training the body up to a better physical state, appeals strongly to the average intelligent person, but the same type of person usually fails to appreciate the full scope and possibilities of such a measure.

In the first place, the average citizen, grumble as he may about business conditions, political conditions and other phases of his environment, is nevertheless fairly well satisfied to leave conditions as they are. This state of mind reflects a certain physiological adjustment which is a sign of mental normalcy.

Conditions Commonly Ignored

It is desirable not to sap the courage or confidence of the average citizen with regard to the outcome of the future, but to put this courage behind intelligent effort to better his condition. An easy going acceptance of things as they are, while a protection against panic, hysteria, and nervous instability, has its obvious dangers; it is not the course pursued by intelligent, resourceful business men in the conduct of their business affairs. The successful business man, who is not merely lucky, combines with perseverance, self-confidence, and the will to prevail, a very canny instinct for finding out what is going on in his business. He knows that no amount of optimism will fill a bank account and that you cannot draw a check against mere hope; there must be material resources upon which to make a draft.

Certain principles of logic and common sense which are applied to every other branch of human activity are almost ludicrously ignored in considering the human body and its adjustments to its environment. That

this complex aggregation of cells, offering splendid invitations to millions of enemies that work unseen, should be permitted to remain uninvestigated, year after year, until these enemies have, at least temporarily, overpowered resistance and given rise to pain or disability, is perhaps the most outstanding and incomprehensible piece of stupidity of which the human race has been guilty in a long range of tragic and costly errors. It is a paradox that man's intelligence is quite as frequently used by him for his injury as for his protection. Intellect, in the history of the human race, has proved to be a very dangerous instrument. Its survival value is often more than compensated by its destructive value.

Primitive man, even civilized man, is often superstitious and guilty of grossly injurious practices because he possesses intellect by which he can misdirect his actions, while the brute, through his instinct, could never be capable of such mistakes.

Primitive man, even civilized man, exhibits cruelty; organizes persecution. Through the intelligence which equips him to scale the heights, he likewise is capable of descending into the depths.

I have no desire to shake anyone's faith in the destiny of the human race as now constituted, but I would urge those who wish to approach this problem in a truly scientific spirit to dissociate themselves from present inhibitions and interfering obsessions and review the history of living organisms in the light of such knowledge as we have. The fact that other races of mankind have failed to attain adjustment and have passed out after far longer trials than any existing race has yet been subjected to warrants caution in assuming that man, as he exists today, is entitled to expect any better fate unless he exerts his intelligence to guard against degeneration and annihilation. Anyone who approaches this problem in other than a cold-blooded, scientific spirit, prepared to view the evidence without prejudice, unimpaired either by fear or optimism, will surely go wrong in his interpretation of such evidence; and not only

that,—he will miss a great deal in practical accomplishment because he will fail correctly to judge the opportunity for corrective work and thus neglect to utilize such opportunity to the fullest possible degree.

Some Wholesome Questions

Let us ask ourselves a few point-blank questions as to the real national need for periodic health examination:

Is it not a fact that such physical examinations as have thus far been made of supposedly healthy people disclosed a very high percentage of physical defects?

Is it not a fact that men whose living habits are likewise considered in relation to their physical state have a similar high percentage of errors in personal hygiene?

Is it not a fact that the correction of these physical defects and the education of these individuals as to more rational hygiene will influence, not only their longevity, but their living capacity and achievement?

If these premises be admitted, is it conceivable that the nations of the world can continue to neglect these opportunities?

Is it not true that the nation which proves so apathetic and unintelligent as not to utilize such opportunities will fall behind others that do?

Can any nation that neglects ultimately to put into operation these rational measures for health protection and physical upbuilding expect to attain world supremacy or even maintain for any worth while or extended period such civilization as it has?

These questions were prominently in our minds during the crisis of the war. The war, for a time at least, profoundly altered our estimates of citizenship. When the call to service came, many men were appalled at the low appraisal that they were compelled to place upon their value as citizens. They were humiliated by their insufficiencies, either physical, mental, or material. Men who had proudly walked the streets, rating themselves pretty high as social units, even regarding themselves as still physically young, were stag-

gered to find that they were pretty nearly ready for the scrap heap!

If this may be said of middle-aged citizens who had cultivated a comfortable sense of self-sufficiency, it may as truly be said of many thousands of younger citizens who have suffered by civilization's stupid neglect to treat them with the same care and consideration that would be ac-

quired from nature and not subject to the operations of its laws as applied to other living organisms. On the other hand, there is too ready acquiescence in the theory of the law of mortality.

The postulate of the "seven ages of man" and the inevitableness of physical changes that we note with each decade after full maturity, is accepted without appreciating that it

of opportunity; there is no denying the penalty for profound neglect.

We have been accustomed to look upon Great Britain as an empire deriving its power pre-eminently from the physical excellence of its citizens. It must be obvious that brain and brawn were required to spread this empire over the earth and its ideals of physical training and physical prowess have always been high; yet the physical tryout of that nation at the time of the war elicited information that staggered the statesmen of the island empire. The spirit of Britain was still there, but, according to the statistics, the flesh was weak. How deeply this lesson was taken to heart by the best friends of Britain is shown by the following quotation of the report of the Committee of the Ministry of National Service, covering the examination of 2,425,184 of military age—from eighteen to forty-two—1917-18:

(1) Thirty-six per cent were placed in Grade I, i. e., approximately only one in every three had attained the full normal standard of health and strength and was judged capable of enduring physical exertion suitable to his age. The remaining 64-65 per cent, or two out of every three examined, over a million and a half in the aggregate, did not attain this standard.

(2) Between 22 and 23 per cent were placed in Grade II, i. e., approximately one in five did not reach the standard of Grade I and were judged to be capable only of undergoing such physical exertion as does not involve severe strain.

(3) Between 31 and 32 per cent were placed in Grade III, i. e., approximately one in every three presented marked physical disabilities or such evidence of past disease that they were not considered fit to undergo the degree of physical exertion required for the higher grades. They may be regarded for practical purposes as the "C3" men of the army nomenclature, whose physical condition became during the war a household word, which bids fair to become a standing addition to our phraseology, at least during the lifetime of the present generation.

(4) Rather more than 10 per cent were placed in Grade IV, i. e., approximately one in every nine or ten were judged to be totally and permanently unfit for any form of military service.

These four inferences may be summarized by saying that medical examinations showed that, of every nine men of military age in Great Britain, on the average three were perfectly fit and healthy; two were upon a definitely infirm plane of health and strength, whether from some disability or failure in development; three were incapable of undergoing more than a very moderate degree of physical exertion and could almost (in view of their age) be described with justice as physical wrecks; and

Grade I represents the full normal standard of health, equal to enduring physical exertion suitable to age.

Grade II represents the group capable of only such exertion as does not involve severe physical strain.

corded good-blooded horses or valuable live stock.

Why,—it may be asked,—is this thing so; why is it that we take good health and long life for granted until it is proved otherwise? I have already intimated that such a state of mind is, to a certain degree, physiological and normal; it represents a certain animal courage and confidence, but it also reflects a certain superstitious, medieval attitude of mind toward the human body; a notion that the human body is apart

implies uncaused action. Must the rise and fall of nations go on indefinitely without any nation showing the intelligence and initiative necessary to keep it on an ascending plane of physical and mental excellence? Is it possible by utilizing scientific knowledge so to mold the destinies of nations that they shall avoid the debacle that history shows has been the fate of all nations and of all races of mankind up to the new stone age? The future must answer this question. There is no denying the wealth

the remaining man as a chronic invalid with a precarious hold upon life.

The Committee then discusses the possible fallacies in the interpretation of such figures and, after allowing for all such possible fallacies, arrives at the following conclusions:

It seems probable, therefore, that the men examined during the year under review may be regarded in the aggregate as fairly representing the manhood of military age of the country in the early part of the twentieth century from the standpoint of health and physique, and that deductions founded upon the observations made at the medical examinations of these men may legitimately be looked upon as a trustworthy criterion of the national health of this period. . . .

War is a stern taskmaster with whom no compromise is possible, as we have learned to conviction during the past four years; convention, prejudice, self-satisfaction, apathy—all alike have to give way before the icy blast of war, which sweeps before it everything except hard facts. It has forced us to face our man-power problem with the close intensity which only a struggle for national existence can evoke. It has compelled us to take stock of the health and physique of our manhood; this stock-taking has brought us face to face with ugly facts and—one hopes—awakened us from the half-hearted complacency with which in the past we have treated our most important asset—the health of the nation.

This is straight talk. It is better than millions of words of national self-glorification and blunt-eyed refusal to recognize not only the sources of national decay, but the factors that make for the decay of civilized mankind. It is true that we had propagandists and extremists who used our draft figures very recklessly and often inaccurately, but it is questionable whether they did more harm than many supposedly competent and restrained scientific observers who put the soft pedal on all these figures tending to show the physical ravages of civilization.

The Factors Obscured

These questions were very much obscured from the standpoint of hygiene and the ultimate fate of the race by comparing peace standards with military standards. The standards of hygiene and of health should be much higher than military standards. It is well known that the vast majority of the men in our own draft who were accepted for full military service were not in good physical trim at the time of acceptance. They required a great deal of physical training and a considerable amount of repair work before they were fit for the firing line. The number declined for full military service approximated 34

per cent; but close to 50 per cent were recorded as having defects worthy of attention and there were, of course, sub-standard physical states and impairments which were not recorded at all among those who were accepted. The Life Extension Institute in its examination of supposedly healthy workers has found approximately 50 per cent in need of important medical

lished in pre-war days they were received with considerable surprise and skepticism, they were so far away from the life insurance figures. The fact that only 10 to 15 per cent of life insurance applicants are declined created the impression that such figures could be accepted as approximating the degree of important physical impairment in the population. Life in-

Grade III presents marked disability and represents the "C3" of the army, a classification which carries a stigma.

Grade IV includes the rather more than 10 per cent who were totally and permanently unfit for military service.

or physical attention and this ratio, we believe, may be accepted as valid for the active working population. It is well supported by such information as comes to us from military records of this and other countries and the records of physical examinations of employees, where these are carried through in a critical manner and not restricted for some special purpose, such as eligibility for employment, life insurance, etc. When the Institute's figures were first pub-

surance standards are business standards; they are sufficient to keep the life insurance mortality within the premium required; they mean this and nothing more.

It may be asked, what does constitute a proper standard of health and physical sufficiency? In fixing such a standard we must not present a mean physical state as determined from analyses of the existing population but rather a standard derived from a consideration of the physical state to

which the human body can be brought by reasonable attention to its care and training.

The Grade I man from the standard of hygiene, health, happiness and living capacity would present the following characteristics: Good posture; well developed, but not overdeveloped, muscular system; blood constituents and hemoglobin within normal range; heart, lungs, blood vessels, and kidneys free from impairment; arteries soft, blood pressure, under varying conditions, within the normal range; freedom from any organic impairment; freedom from head infection; teeth, nasal cavities normal and free from obstruction, impairment of the mucous membrane; tonsils normal in structure and function; head cavities, accessory sinuses, middle ear, etc., free from infection; vision normal or at least susceptible to correction to prevent eye strain; hearing normal; freedom from intestinal stasis, only one bowel movement a day usually indicating intestinal stasis; skin free from infections, eruptions, or other pathology; feet free from bunions, distortions, weakened arches, or impaired support,—able to carry a man as far as he wishes to go in a day's walk or climb without pain or untoward symptoms; freedom from nervous affections; brain and nervous system in sufficient poise to carry a man successfully through his business and social relationships; freedom from bacterial or parasitic infection of any kind; and freedom from toxic influences.

The Life Extension Institute has examined more than 150,000 people and it has never found a human being who could measure up to these requirements. Only about 10 per cent of the people examined may be said to have had minor defects; the other 90 per cent ranged from defects perhaps not menacing but of real importance down to those who are actually far advanced in disease and, in fact, in imminent danger, but often without consciousness of it. People gradually become adjusted to impaired health until their notion of what constitutes health is distorted. The only proper standard for the hygienist to set up is that of abounding health, a physical state of high resistance and one in which the period of physical freedom is not limited to a single decade or less but extended to many decades. There is no evidence either from biological sources, clinical sources, or vital statistics to indicate that modern man is through evolution attaining a higher physical type. Professor E. Grant

Conklin has maintained that there is some evidence to the contrary; in other words, that man's evolution has reached its limit so far as modern man is concerned and if any improvement is to be brought about it must be through man's directive intelligence.

The Field Is Open

Through eugenics, through prenatal care, post-natal care, child hygiene, adult hygiene, community hygiene, we have the right to hope that a higher physical type may be attained, or at least that such latent possibilities as there are in the present type of man may be fully utilized. There is, of course, a limit to what nurture can do. There are definite limitations imposed by heredity. For this reason we must in this country consider the types that we admit to our shores and what may be possible in the way of preventing the multiplication of the grossly unfit. With these qualifications it may be said that the most important fundamental measure to be relied upon in prolonging human life and making it more livable is the thorough-going periodic survey of the lives and bodies of our citizens and the education of these citizens in the art of living healthily and happily.

The Mortality Rates of College Women

Given proper economic, educational, and environmental conditions, the health and longevity of the people will be increased. It would be expected, then, that any group of persons who exemplify such favorable conditions in their mode of living would live longer than others who do not have these advantages. That this fact is so is shown by a recent study of the mortality rates of college women.* Here is a class of persons who have unusual opportunities to learn how to adjust themselves properly to work, to rest, to amusement, and to living conditions generally. The results of the study, which was made by Miss Myra H. Hulst, statistician with the American Red Cross, show that the death rates of college women are lower than those of any other class of women which has previously been studied.

In order to reach this result, data were collected on all the graduates of three women's colleges—Vassar, Wellesley, and Smith. All alumnae of these colleges were included, start-

ing with the class of 1867 for Vassar and 1879 for both Smith and Wellesley. The number of graduates was 15,561 and the years of life totaled 204,553. It was found that the general death rate for the period of life included—20 to 64 years—was 3.24 per 1,000. This is a remarkably low rate. It is less than one-third the death rate of women of this age group in the United States registration area, which is estimated to be about 10 per 1,000. The figures for Smith alone—between the ages of 20 and 59 years—are even lower, being 2.55 per 1,000. Vassar has a rate of 4.16 per 1,000—between the ages of 20 and 69 years—and Wellesley a rate of 3.14—between the ages of 20 and 64 years.

The results when compared with rates for women in the registration area of the United States were lower in every age group. The figures for college women were also compared with those for teachers in New York City and the two were very much in accord. These teachers were found to have the lowest rates of any class of New York City employees in a study by George Buck on Teachers' Pensions in 1916.

The results of this study are significant in that they indicate what might be accomplished if the advantages which college women enjoy could also be extended to all other classes.

JAMES A. TOBEY.

Appropriations for Social Hygiene

The Senate voted to strike out the \$40,000 for registration for the interdepartmental Social Hygiene Board, inserted as an amendment to the Sundry Civil Appropriation Bill. The appropriation for \$300,000 for the continuance of venereal disease control work was transferred from the Interdepartmental Social Hygiene Board to the Public Health Service. If this action is approved by the conference committees, the activities of the Interdepartmental Social Hygiene Board will cease after July, and all venereal disease control work of the government will be under the direction of the Public Health Service.

Gains in Fresh Air Schools

Philadelphia Health Council and Tuberculosis Committee reports concerning the 297 undernourished children who are in open-air school classes. Both boys and girls have gained on an average of 1.7 pounds in weight during the period covered by last three months.

*Mortality Rates of College Women. M. M. Hulst. Quarterly Publication, American Statistical Association, March, 1921.

The Relation of Posture to Individual Health*

A Tendency to Get Away from the Non-thinking Acceptance of the "Customary" Working Postures

BY EDITH HILLES, BUREAU OF WOMEN IN INDUSTRY, NEW YORK STATE INDUSTRIAL COMMISSION

FATIGUE—"the danger signal," blazes forth an advertisement; "Fatigue—the greatest cause of waste in industry today," says a government report. From all sides it is coming; the world is beginning to think in terms of fatigue and its elimination.

It is because of its relation to fatigue that the question of posture in industry has come to the fore. Until late years, posture has been studied for the most part as it affected school children. It was easily recognized that a child must not work too long in one position, that the desk and desk chair must be of proper height and modeled to give the necessary support. Non-adjustable double desks are relics of the dark ages in education, and constant improvements are being made in an effort to secure for the child the possibility of correct posture. Yet the worker is at his task many more hours than the child is in school, and the necessity for insuring to him the possibility of good posture is fully as important.

For years we were in the stage of shortsighted industrial development when "posture" meant only "give the girl a seat." Sentimental campaigns for "seats for salesgirls" were recognized as justifiable, but a round-topped stool was considered as good as a rocking chair, and the idea of any scientific study of the posture of a worker with a view to eliminating unnecessary fatigue was not considered, save by pioneers like Dr. Goldthwait, Mr. Spaeth, Mr. Gilbreth, the American Posture League, and a few industrial engineers.

Efficiency Eliminates Waste

However, "necessity is the mother of invention," and where a manager has been forced to secure maximum production, he has inevitably come to see the need of some study of the posture of his workers in an effort to eliminate that fatigue which pulls

down his production, lowers his standards of work, and increases his accident rate. It is a part of efficiency to eliminate waste, whether it be waste in material, waste in motions, or waste through unnecessary fatigue.

Many work conditions—lighting, ventilation, clothes, noise or speed—may cause fatigue, and there is no doubt that bad posture is one of these causes, and that fatigue brought about in such a way is in large measure preventable.

Fatigue, true to the advertisement, is indeed a "danger signal." It produces in the body poisons which gradually slow down the capacity for doing work. However, the body is so constructed that it purifies itself during rest, and the poisons that have clogged its bearings are carried off. The problem, then, is to so maintain a balance between work and rest that nature may have a chance to maintain her balance between breakdown and repair in the human body. Accident and production statistics would indicate that this balance is seldom kept in industry today.

A machine in some measure can protect itself. It stops running if it is not cared for; consequently, we give it the best care of which we are capable. Machines are expensive.

They are difficult to replace. They must be oiled at regular intervals and cared for scientifically. The human body is unable to protect itself in a similar way. Its slowing down is more gradual and it can be forced until repair is impossible and it is ready for the scrap heap. Until we come to realize that human beings are more expensive discards in industry than are machines, we will fall short of intelligent industrial development.

The fundamental need in industry is to prevent the worker from reaching a condition of over-fatigue. A little fatigue is easily overcome, if rest or change is supplied immediately. Twice the amount of fatigue requires *more than twice* the amount of rest, and so on, until finally a state of excessive fatigue requires a rest period that may need to be prolonged indefinitely. It is this fact which lies at the basis of the great unnecessary waste from accumulated fatigue.

"Our body is not constructed like a locomotive which consumes the same quantity of coal for every kilogram-meter of work. When the body is fatigued, even a small amount of work produces disastrous effects. . . . The workman that persists in his task when he is already fatigued not only produces less effective work, but receives greater injury to his organism."

Adelaide T. Crapsey Company.

Certainly imagination was used in the equipment of this handfinishers' department of a clothing factory. The experiment in seating is an interesting change from the usual bent-double position of the hand worker in a garment factory.

*The first of a series of articles on the relation of posture to industrial health compiled from the data contained in the report of the Bureau of Women in Industry of the New York Industrial Commission on Industrial Posture and Seating and the illustrations used are from those courteously furnished this Department for their Bureau.

The height of the elbow in relation to the table is the same, sitting or standing. Correct posture assures the minimum of effort and strain. Fatigue results from the cumulative effect of unnecessary tensions.

Scientific American—Frank B. Gilbreth. Note the backward slope of the seat and the circular foot rest under the bench. Designed for drafting work by Mr. E. E. Barney of the Remington Typewriter Company.

A bulletin² just prepared by the Bureau of Women in Industry of the New York State Industrial Commission has gathered together the most significant material on the study of posture in industry and the need for further study and establishment of scientific standards, as well as the experiments now being made in particular plants, or laboratories.

In defining good posture, statements from the American Posture League and from Dr. Joel E. Goldthwait of Boston are taken as authoritative:

Good standing posture is defined by The American Posture League as "one in which the different segments of the body—head, neck, chest and abdomen—are balanced vertically one upon the other so that the weight is borne mainly by the bony framework, and a minimum of effort and strain is placed upon the muscles and ligaments. In this posture, under normal conditions, the organic functions—respiration, circulation, digestion, etc.—are performed with the least mechanical obstruction and with the greatest efficiency."

Good sitting posture Dr. Goldthwait urges as "the thing which should always be insisted upon in the use of the body in any way is that the body should be kept straight from the hips to the neck and should not be allowed to flex or bend at the waist line. Any position which allows this lowers the vitality of the individual, leads to strain of the back, and naturally, lessens the efficiency of the worker."

In correct position leaning forward, the feet should rest comfortably on the floor or foot rest, the body should be kept straight from the

hips to the neck and the inclination forward should occur entirely from the hips.

In correct position leaning backward, the feet should rest comfortably on the floor or foot rest, the pelvis should be as close to the back of the chair as possible, to prevent sliding forward, and the small of the back should be supported.

There is much variance in medical opinion as to the effects of bad posture on the health of the worker. Dr. Eliza M. Mosher³ claims that the "habits of posture that produce round shoulders and forward drooped head not only lessen the space in the chest for the lungs, but may inflict great injury upon the organs within the abdominal cavity. While a variety of conditions are active in the production of a downward displacement of the organs, this bent forward posture of the body, especially in individuals of tall and slender build, is conducive to it. Normal folds and turns in the digestive tube are deepened by the

folding inward of the wall of the abdomen on the belt line and by the downward crowding that takes place. The canal is thus partially closed in places, with consequent damming back of its contents, thereby giving time for the colonies of bacteria, always in residence there, to multiply and the toxins they produce to be carried into the tissues of the general body in excess of elimination. As a result, constipation, diarrhea, flatulence, disturbances of circulation, headaches, nervous irritability, and, most marked of all, *fatigue out of proportion to effort expended*, lessen the efficiency of the individual and often make life a burden."

In the sideways slouch position the weight is more on one foot than on the other in standing, and more on one hip than the other in sitting. "The ribs are crowded together between a low shoulder and a high hip on the one side, and proportionately separated upon the other side between a high shoulder and a low hip. The wide separation of ribs on the high shoulder side limits their motion and thus interferes with the entrance of tidal air, especially at the apex of the lung on that side. The tubercle bacillus seems to find a good place for growth and multiplication in this region; certain it is that in a large number of persons suffering from tuberculosis this posture is the habitual one and the disease first invaded the apex of the lung on the side of the high shoulder. . . . In girls and women, with the marked slouch habit, the fundus of the uterus is almost invariably found lying beyond the median line of the body *toward the high hip side*, crowded over by the intestines which fall into the larger space on the low side."

The conclusions reached by the report of the New York State Industrial Commission may be briefly summed

A simple method of raising an ordinary chair to a height that enables the worker to sit or stand. Special devices are unnecessary if attention is given to the individual worker.

Scientific American—Frank B. Gilbreth. An adjustable table top is shown here. The seats and foot rests are very bad. (Report of Great Britain Home Office on "Seats for Workers.")

up as (1) that posture should be varied; and (2) that work conditions should be such that correct posture is possible, this result being assured by providing a physiologically good chair, and by arranging the different parts of the work place in the best possible relationship.

What a Good Seat Is

What a physiologically good seat is, and what relationship the different parts of the work place should bear to each other, will be discussed in articles following this one, together with examples of experiments in seating, which have been tried.

The importance of the first conclusion—variation in posture—cannot be too strongly emphasized. Continuous standing and continuous sitting are both injurious. Most of the known facts would seem to indicate that continuous standing is more harmful to women than to men.¹ It is nevertheless true that "varicose veins, knock-knees, and deformities such as flat foot, are frequently found among men pressers, apprentices of bakeries, motormen, and conductors, and it is more and more recognized that the determining factors are the demands of the particular industrial process, rather than the sex of the worker."²

"The effects of a constrained position combined with a sedentary life, are very injurious. This is especially seen in weavers, shoemakers, engravers, watchmakers, tailors, lithographers, etc., all of whom are obliged to assume a more or less constrained attitude, which interferes with the proper distribution of the blood supply, and is liable to be followed by internal congestion; but perhaps the greatest harm results from deficient movement of the chest and consequent interference with normal respiration. As a matter of fact, many of these artisans suffer from phthisis, constipation, dyspepsia, and hemor-

A small, collapsible table placed on a bench of ordinary sitting height. The legs of the table fold, and it can be pushed out of the way or used as in Figure 10.

Cluett Peabody Company.

Raised chair and swinging foot rest which is adjustable in height. The chair would be more comfortable without the knobs on the front of the seat.

rhoids, and all have a low average of life."³

The great difficulty is that most industrial processes have been handed down in such a way that one position is accepted as the only possible position, when, as a matter of fact, there are comparatively few operations which intrinsically demand continuous "one position" work. There has been next to no effort to scientifically "fit the work to the worker," except where it has been realized that unnecessary fatigue is needless loss, and that in order to reduce fatigue, work must be "physiologically balanced." A little ingenuity and imagination will many times make variation in posture a simple and practical possibility.

The testimony of firms who have displayed such ingenuity has been collected in the report referred to. One company manufacturing laundry machinery has now designed a machine with a platform and stool attached, and a pressing machine (Fig. 4) is now on the market which holds out as one of its best selling points the fact that it can be operated from either sitting or standing position. Another machine company claims to have especially designed the height of their machines so that the operator could either sit or stand at work. The experience of the packing department in a large chewing gum factory furnished an interesting suggestion. The packages of gum were being packed into glass jars which stood

almost a foot high from the work-bench. The packages of gum stood upright in the jar, and it was found that they could be packed more easily with the jar laid on its side, since the feeding motion in filling the jar was more easily done from the side than from the top. This lower position made it possible for the packers to sit down at work, and so the job became one which could be done either from a standing or a sitting position. Many instances of similar adjustment could be cited where the placid acceptance of the customary positions of doing things has prevented the introduction of simpler, more useful and more productive methods.

Positions May Be Varied

When it is not possible to vary the worker's position while at work, whether because equipment or machines have been constructed with no thought of allowing variation, or because the operation is one at which only one position is possible, other means have been found by which the worker may be given the opportunity to change his position.

One such means is the establishment of an *interchange of processes* whereby the worker changes not only his position, but his work. In a small plant or with different types of hand work, this is easily arranged.

Many firms are at present regulating the handling of supplies in such a way as to force the worker to rise from an operation at which he has

The Lamson Company.

In an old-fashioned department store tube-room, the girls stood or walked from tube to tube. The modern appliances include chairs which enable the workers to sit or stand.

been sitting and take his finished articles to another department, where he secures fresh material for work. Thus, of necessity, he rises, walks about, and changes his position.

A production engineer tells of one instance in a clothing factory where the workers, on piece work, never paused during rush hours, or rose from their chairs. Supplies were brought to them, and on a long wall behind them, their wraps were hung. At noon, they reached for their lunches, usually carried in their coat pockets, and ate at their machines. In his reorganization of the plant he removed the wraps to a distant part of the floor, and regulated supplies in such a way that the girls were obliged to rise and walk about at intervals. Instead of considering this wasted time, it was definitely planned as a means of increasing production by giving the girls a chance to vary their positions and rest their tired muscles.

Rest Periods Required

The introduction of rest periods is by far the most popular means employed to secure variation in posture. Where compulsory rest periods have been introduced, workers have not infrequently asked to have them eliminated and to leave that much earlier at the end of the day. Such a plan, of course, in no way brings the same

results; for the rest periods should be planned scientifically to make a break in the work at the time when a change is most needed. Nor is it enough to simply "permit" the rest. If the job has been a standing one, proper seating facilities should be provided for the workers during rest periods, or, if the job has been one requiring continual sitting, it should be made possible for the workers to walk about during the rest period. Some companies have gone so far as to introduce calisthenic drills outdoors, when the weather permits, during the rest period. The rest period should introduce variety and change.

Reynold A. Spaeth of Johns Hopkins University gives one instance of the introduction of rest periods in a pressing room where women had been standing at their boards all day. Rest periods of five minutes duration, one in the morning and one in the afternoon, were not only introduced, but comfortable chairs were provided to be used during these periods. The result was that an average gain in efficiency of 20.3 per cent was made by a group of four skirt pressers who were studied before and after the introduction of these rest periods. Without rest periods, the average efficiency of the four operators for nineteen days was 70.2 per cent; with rest periods, the average efficiency of the same group for nineteen days was

90.5 per cent. Undoubtedly this astounding increase in efficiency was due to psychological as well as physiological factors, but the fact is undisputed that a plan enabling workers to change their positions at intervals during work hours has a definite and often startling effect on output.

In the last analysis, industry is a problem in the conservation of man power. In seeking to intelligently meet the rapid development in industrial practices are we forever to accept the trial and error method, or are we to build on the accumulation of evidence which scientific study is gradually giving us? Custom is not perfect *per se*. To get away from the non-thinking acceptance of "customary" working postures, and to see to it that the worker varies his position, is becoming a simple and important principle in any plan for the elimination of unnecessary fatigue.

Highways and Health of Rural Communities

BY LEE LAMAR ROBINSON, FORMERLY PUBLICITY DIRECTOR, TRANSPORTATION DIVISION, COUNCIL OF NATIONAL DEFENSE, WASHINGTON, D. C.

THE so-called child welfare special, represented by traveling hospitals and laboratories, combined, made possible through the use of specially built bodies on motor trucks, which are gradually becoming familiar to the people of the rural sections and are meeting with widespread approval and success, naturally causes the question to arise, "Why are these traveling hospitals needed in this day and age, and in these United States?"

The answer is to be found in the fact that, due to the lack of improved highways of sufficient mileage, a tremendous number of the people of the United States are being denied prompt and efficient medical care as a result of the inability of physicians or nurses or both to reach patients in time always to be of service. Again, due to the same lack of good roads,

records show that physicians fewer and fewer in number are willing to establish themselves for practice in or near widely scattered areas, particularly where these areas do not furnish quick and convenient travel by highway.

Mr. Wilson, while President, in an address to Congress in which he favored an extension of the good roads movement, coupled this recommendation with a suggestion that steps be taken which would make possible fuller provision for sanitation in rural districts, and the building up of needed hospitals and medical facilities in these localities. The former President, therefore, it would seem, was fully cognizant of and in sympathy with, such development as would place within safe and reasonable distances from doctors, hospitals, and nurses, those people of this coun-

try living in isolated sections. President Harding, since assuming office, has on different occasions declared for an efficient road building program.

Poor highways, it has further been shown, make the death rate higher, preclude medical attention, and increase mortality. The Red Cross, the Y. M. C. A., the Y. W. C. A., and other similar agencies have been and are doing yeoman service to the end that rural folk be provided medical attention, particularly the present and prospective mothers and the little ones; and, through the use of traveling hospitals such as are suggested above, and of motor machines which today are not only mobile but hardy, such associations are sending into sections which know practically nothing or at best all too little of scientific medical treatment and nursing, cars for the purpose of giving instructions

not only to individuals but, through lectures, pictures, etc., in sanitation and the care of the health, to the communities.

Surveys made by different departments of the government show two causes for the lack of proper medical treatment of people in the extreme rural districts, particularly in the great Northwest, the first and most important of these being the practical inaccessibility of tens of thousands of farm homes from those skilled in medicine and surgery. Again, in answering the question, "Does the country need doctors?" Federal statistics also show that 3.7 per cent of country children are affected by tuberculosis of the lungs as against about 1 per cent of city children; that the eye defects in country children are four times as numerous as in

est of the general public in rural health conditions and plans for improving them, is made apparent. It is an interesting fact that about two-thirds of the 160,000 or more doctors in the United States now own and operate motor machines, thus putting them in a position to very greatly extend the area in which they may practice, provided the Federal Government and the states, as well as the counties and the communities, see to it that these doctors are provided such roads as will enable them to serve efficiently the greatest number of patients.

It has been very well said that "Good roads pay dividends in health as well as in prosperity." Along these lines, information gathered by the Transportation Section of the Council of National Defense is of interest and value as tending to focus attention

(Photo by J. F. Smith.)

This pictures a road which is the main highway between twenty thousand people and the railroad. The farmer's mule has fallen exhausted when he is still twenty miles from the market.

the health not only of certain individuals but groups in cities and also in rural districts. This would seem to offer an interesting subject for detailed inquiry and discussion."

A report from North Carolina says that public health education is being directed to the various counties in the state at this time, "the good roads counties getting it first."

Reports from West Virginia suggest a serious situation in that people in different localities, which are distant from centers of population, have presented petitions to the state health officer asking that men with but few if any qualifications as physicians be permitted to practice without molestation, due to the fact that it is impossible to get physicians to locate in these sections. One such report concluded: "Better roads and quicker transportation would doubtless bring about better conditions."

From Illinois comes this information: "Rapid means of transportation over good roads is doubtless of advantage in bringing about a better milk supply through quicker delivery and of advantage in making communities more accessible to county or municipal nurses and to physicians. Transportation of patients to hospitals by means of ambulances or otherwise is practically out of the question at certain periods of the year in certain sections."

Congress and Highways

Two subjects which will be well to the forefront in the special session of Congress, now in session, will be that of the public health and of highway development. While the two will not be related from a legislative standpoint yet those members of Congress who are interested in securing further federal appropriations to aid the states in road building will use, as they have in the past, among other arguments the vital relation of highway extension to the health of the

(Photo by J. F. Smith.)

What chance for emergent or regular medical and nursing care have the people who live on a road that requires a four-mule team to pull the mail wagon? Two counties in Kentucky are so isolated on the road served by this mail wagon.

those of the city; that ear defects are more than five times as many; enlarged tonsils, four times, and curvature of the spine, twenty times as numerous.

Physicians Automobile Owners

As every death is an economic as well as a personal loss, from a selfish standpoint if from no other, the inter-

upon situations now existing in various States from a health standpoint, and some of the most vital factors in relation thereto.

For example from Kentucky comes a suggestion that "The number of physicians in the rural districts is rapidly decreasing . . . and especially does this apply to sections not having good roads. It is impossible to organize rural community hospitals where there are no good roads."

From Louisiana: "If appeals from rural districts for physicians can be used as evidence the hardships of bad roads certainly must prevent physicians from practicing in rural communities because there seems to be a large number in need of this help."

Need of Inquiry Suggested

New York: "The importance of transportation facilities including highways, are doubtless of importance both directly and indirectly to

(Photo by J. F. Smith.)

This mountain stream is followed by a trail which is the only highway leading through a remote mountain district in Kentucky.

nation. Investigations, begun during the last administration, into health conditions will be continued by experts under the new administration.

As these investigations proceed those in charge will inevitably run into the problems involved in the providing of ample and substantial thoroughfares, whether urban or rural. Social workers, also active in Washington, have long since learned that the colonization of great numbers of people in congested areas is in direct conflict with movements looking to the promotion of the health of the country. Therefore, they have become converts to the movements looking to the location of city workers in the suburbs. This plan spells wider areas in which the children may play, breathing spells for the man who toils in factory or store during the day, and the possibilities of garden spots which cultivated, mean both health and recreation.

The advent of many modest priced

motor cars has made it possible ere this for city workers to live in the open, but one handicap has been found in the failure of county and municipal authorities to provide roads which make trips to and from town agreeable and of short duration. The result has been that far-sighted realty men as well as those interested from an unselfish standpoint, in placing families outside the city proper as dwellers, have come to realize roads must be provided to give the open spaces that are necessary to attract the people.

Back to the Farm Movement

Again, a well backed movement is on foot to interest immigrants in country life that the production of foodstuffs may be increased and also the congestion in the cities decreased. The wonderful highways of the European countries are known to many in this country and these realize that no stronger appeal can be made to the

immigrant in seeking to interest him in a life on the farm than to provide such highways as will give the companion loving European, opportunities for getting into frequent touch with his fellows.

As a result, the highway movement is linked up not alone with the interests of the man in an isolated section of the country from a standpoint of health and recreation but also with the present and the potential dweller in the environs of our cities. Again, to the man whose interests require an urban residence the highways leading out to the open country have an appeal today, due to the motor era, which they never had before. They make accessible drives which bring both mental and physical relaxation and put in close touch the golf course and the picnic ground, two recognized adjuncts to better living conditions, and better living conditions mean invariably a healthier and stronger nation of individuals.

Public Health Nursing in New York

Growth and Present Organization of the Nursing Division of the State Department of Health

BY MATHILDE S. KUHLMAN, R.N., DIRECTOR, DIVISION OF PUBLIC HEALTH NURSING, ALBANY, N. Y.

WITH the reorganization of the State Department of Health in 1913 a Division of Public Health Nursing was created by the legislature with salaries for but four state nurses. In the following year provision was made for a director of the Division and three additional nurses. The subsequent legislature made no provision for the salary of a director or for additional nurses.

Owing to the great epidemic of poliomyelitis in 1916 it was necessary to provide special state nurses for clinic and follow-up work among those crippled by the disease. This corps consisted of eight nurses and two muscle testers. The legislature of 1919 increased the number of state nurses and provided for the salary of a director. The Division of Public Health Nursing at the present time consists of a director and twenty-six supervising nurses, and two muscle testers.

This growth in the personnel of the Division has been largely due to the recognition by the people of the state of the importance of the work of public health nurses as is clearly evidenced by the fact that the number of

local nurses outside of the city of New York has increased from some 135 in 1913 to more than 1,050 at the present time.

The supervision by the state of the work of local nurses, while not specifically defined by law, is clearly indicated by the relation which the

Following a demonstration visit, the public health nurse makes an instructive visit (N. O. P. H. N.).

local nurse bears to the local health officer over whom the State Department of Health has been given supervision.

Owing to the ever increasing and diversified demands made upon the nursing division of the State Depart-

ment of Health, it has been found of advantage to assign a part of the state staff to special and others to the supervision of general work. Thus one nurse is assigned to each of the following divisions of the State Department of Health: Child Hygiene, Tuberculosis, Communicable Disease, Venereal Diseases, and Public Health Education. One nurse gives full time to the supervision and instruction of the 520 midwives of the state and to the inspection of fifty-two day nurseries outside of the city of New York. Another works in cooperation with Farm Bureaus and Granges, Parent Teachers' Associations, Civic Clubs, and the like, giving lectures and teaching classes on the subject of home nursing, first aid and kindred subjects. One supervising nurse assists the Acting Director of Public Health Education in editing a *Public Health Nurses' Bulletin*, which is issued monthly by the State Department of Health for distribution to nurses throughout the state. This *Bulletin* contains articles of instruction and information on such subjects as mental hygiene, nutrition of school children, record forms, etc.

The nurse assigned to the Division of Communicable Diseases assists the Sanitary Supervisor and local health and educational authorities when called upon by them in controlling outbreaks of communicable diseases in the various districts throughout the state. In the conduct of this work instruction is given by the nurse to school teachers and lay persons in the prevention and control of communicable diseases and, when necessary, she assists the Sanitary Supervisor or local health officer, or both, in making sanitary surveys in order to locate foci of prevailing diseases, such as tuberculosis, influenza and typhoid fever. The organization of the Division of Public Health Nursing is sufficiently elastic in the event of severe outbreaks of epidemic diseases throughout the state so that in an emergency the entire nursing staff or any part of it may be placed at the disposal of the Director of the Division of Communicable Diseases.

On the five largest of the Indian Reservations of the state there are four public health nurses who cooperate with the reservation physicians in the care and teaching of the Indians. In addition to bedside care they give instruction in prenatal, general public health nursing, and part of their time is devoted to school work.

In the after-care of infantile paralysis the state has been divided into eight districts and one nurse assigned to each. Periodical clinics are conducted by the orthopedic surgeon of the State Department of Health, assisted by these nurses, who arrange for clinics and make follow-up visits to the patients, giving instruction in proper muscular exercises and in the adjustment of braces and orthopedic appliances.

It has recently become possible for the Division of Nursing to place in effect a plan whereby one supervising nurse is assigned to each of the fourteen State Sanitary Supervisors' districts, her duties being to assist the Sanitary Supervisor and local health officers in the development of public health nursing where such is not or-

Eight Nurses and two muscle testers constitute the corps whose function it is to look after the child cripples of New York State (N. O. P. H. N.).

ganized and to give assistance to those nurses who are already in the field in the performance of their work including instruction in the method of filing reports.

The number of local nurses has increased so rapidly as to make it inevitable that many of those now in the field have had little or no training in public health except what they have been able to gather by experience and reading. It is therefore very essential that insofar as possible the state nurses shall be kept constantly in touch with the work of the local nurses, helping them to solve the difficulties in the performance of such of their duties for which their training has not especially fitted them. It is hoped that in the near future short courses of instruction in public health for nurses already in the field will be provided. This is of such fundamental importance to local communities and to the health work of the state at large that it is to be hoped that the plan will not be long delayed.

Finally, the Division of Public Health Nursing is cooperating with the Bureau of Nursing of the Atlantic Division of the American Red Cross and with the Nursing Division of the State Charities Aid Association in endeavoring to standardize the nursing work of the state and to secure qualified public health nurses to supply the demand. Through conferences with these organizations the activities of the nurses in the field is coordinated and planned to prevent the duplication of effort. The agreement with the American Red Cross is as follows:

(1) That local American Red Cross

nurses forward a copy of their monthly statistical report to the Director, Division of Public Health Nursing, State Department of Health.

(2) That American Red Cross nurses attend such conferences of nurses as State Department of Health district supervising nurses might call together within the district, if the conferences are not too frequent, and the nurses' work permits them to get away.

(3) That State Department of Health district supervisors will receive every consideration from American Red Cross nurses if they wish to make visits of inquiry or inspection.

(4) That American Red Cross nurses may take advantage of the opportunity to consult with State Department of Health district supervisors about their work, other than matters of Red Cross organization.

(5) That American Red Cross nurses render occasional service in adjacent territory, at the request of the district supervising nurse, State Department of Health, if their work permits, and if such requests are not too frequent.

(6) That occasional conferences will be held with the Director of Nursing Service, Atlantic Division American Red Cross, and her supervisory staff with the Director, Division of Public Health Nursing, State Department of Health, and her supervisory staff.

(7) That the Director of Nursing Service, Atlantic Division American Red Cross, and the Director, Division of Public Health Nursing, State Department of Health, confer more or less regularly in order to be better informed of each other's work and thereby to avoid confusion and make the best use of both services.

In addition to the local communities now supplied with nurses there are several hundred more who would be willing to pay for the services of a nurse if the latter could be secured. The State Department of Health feel that there is no more important factor in stimulating the interest of the people in public health than the presence of a well-qualified public health nurse, and to this end the Division of Public Health Nursing of the State is bending a large part of its energy.

Principal Disease Conditions

THE February *Statistical Bulletin* of the Metropolitan Life Insurance Company reports as paid during 1920 nearly forty-seven million dollars in the payment of death claims, more than three-fourths of which amount was paid on account of deaths from ten causes which are largely preventable or postponable.

More money was disbursed on account of tuberculosis than for any other disease. Despite the fact that the death rate for tuberculous diseases in 1920 was the lowest in the history of the company, and was two-fifths below that of 1911, more than six and one-half millions were paid for death claims resulting from tuberculosis. There is still much room for extension of the educational campaign which has been carried on for years to show the importance of personal hygiene, of early recognition of incipient cases, and of the fresh air method of treatment.

Pneumonia ranks second in importance in amount paid for death claims. The sum was more than five million dollars. Many of these pneumonia deaths were due, primarily, to influenza, which continued to be, on its own account, one of the principal causes of death; it was responsible for the disbursement of well over three million dollars. One dollar of every fifteen disbursed was paid on account of deaths definitely reported as due to influenza. The total for influenza and pneumonia combined is even higher than for tuberculosis. The amount was more than eight and one-fourth million dollars.

Over five million dollars were paid on account of organic heart disease.

There is a promising field for public health work in the dissemination of information to cardiac patients on personal hygiene by means of which many of these deaths could readily be postponed.

Over three and one-half millions were paid in the settlement of death claims for cancer. One death in every eight of women and one in every fourteen of men over the age of forty years is from cancer. There is much to justify a more intensive effort on the part of communities to disseminate knowledge concerning the early symptoms and treatment of the disease.

The amount disbursed on account of the various diseases and conditions arising from pregnancy and childbirth was nearly one million dollars. It is evident that still greater efforts are called for in such directions as the education of pregnant women in hygiene, the supervision of midwifery, and even more than these, the extension of prenatal and postpartum nursing care.

Bright's disease and cerebral hemorrhage were other important factors, for which, together, about six million dollars were disbursed. Deaths from these diseases are, in the majority of cases, those of older persons; nevertheless many of them are postponable, especially those from Bright's disease.

Life Has Economic Value

There were disbursements of nearly four and one-half millions of dollars on account of deaths from violence. This is in spite of the fact that the death rates for suicides, homicides,

and accidents were lower than have obtained for many years. These rates are still needlessly high in the United States.

These figures bring home strikingly the economic value of human life. They show how great are the losses from conditions which are, to a great extent, preventable. But the losses suffered by communities are far greater than those of the insurance companies. The average amount of insurance carried is far below the economic value of a human life. Life insurance companies have found that it is profitable to engage in health conservation work because such effort prevents or postpones deaths from many diseases. Certainly then, the organized public health agencies of the Federal, state and municipal governments, which have more at stake than have insurance organizations, will be justified in spending more money on properly directed effort in public health work.

The accompanying table shows the amount of money disbursed in death claims on account of each of the more important causes of death.

Death Rates Among Medical Men

The *Journal of the American Medical Association* recently analyzed the deaths of medical men in the United States during the preceding year. General diseases accounted for 267 deaths, diseases of the nervous system 271, circulatory 404, respiratory 266, digestive 70, genito-urinary 154, senility 77, suicide 32, accidents 102, homicide 14, sequels of surgical operations 74. Organic heart disease and cerebral hemorrhage were among the most frequent assigned causes for death. An analysis of this kind properly correlated with the factors would be significant in maintaining the health of physicians as a class.

Industrial Disease Compensation

The *Monthly Labor Review* for January, 1921, reports that the Labor Gazette of Ottawa for November publishes a list of industrial diseases approved by the government under the Workmen's Compensation Law of New Brunswick (1918), which authorized compensation for industrial disease. The list includes poisoning from sulphur, anemia, and carbonic gas, as well as infections from handling sugar, among the more unusual poisons. Compensation in industrial disease presupposes an industrial toxicology.

The Nation's Health Initiates a Broadened Health Program

THE transition of this magazine to a journal of broad scope in public health is completed and this issue marks its appearance under the new name, THE NATION'S HEALTH, which announces the policy to be pursued.

The scope of the new magazine is inclusive of all the measures which prevent disease and promote and condition health. Special emphasis will be placed upon organized agencies, public and private, which care for the health of groups of people and are therefore in a position to promote health by comprehensive measures. Industrial and commercial groups, students in schools, academies, universities, dormitory groups, and inmates of institutions may be protected and benefited in their health through organization much more effectively than by individual effort. Those who have control of a large part of the time of groups have an opportunity for public service which has been all too little realized. If every industrial manager, school director, head of a boarding institution, or the superintendent of a benevolent institution were to organize for the health of the groups under their care, a mighty transformation would take place in the health of the nation. Such a change is to be looked for in the organization of all social and industrial groups into better health units. To the field primarily of organized effort for health this magazine will be devoted.

Internationalism of Disease Calls for Collective Effort

THE obvious fact that disease is international has remained dormant in the minds of the leaders of the nations. Each country has acted by and for itself in fighting disease. Each country has built with more or less success a wall of inspections and regulations to prevent the importation of disease. Yet disease spreads from nation to nation—now typhus, now bubonic plague, and again cholera or yellow fever menaces the world from infected quarters.

In an illuminating article in the *North American Review* for March, Dr. Richard P. Strong of the League of Red Cross Societies points out that "even in times when communication by land and sea was extremely limited, epidemics often spread from country to country as is evidenced by the pestilences of plague, cholera, typhus, and smallpox which ravaged Europe in the Middle Ages, but with the bridging of space by modern means of transportation the danger of the spread of a number of the most serious infectious diseases evidently has been greatly increased."

America, though isolated geographically, has had typhus and plague imported within the year in spite of stringent regulations and vigilant inspections. Warnings come out of Central Europe that "unless typhus is checked at the source in that region it will spread throughout the world."

"The war against disease is a world war," declares Dr. George E. Vincent in this issue of THE NATION'S HEALTH. "Commerce carries dangerous infections as well as goods and ideas. The health problems of the remotest land concern all peoples. More and more nations are coming to recognize their interdependence in health, as in industry, government, science and culture."

The plain facts of disease infections are operative internationally and call for united action by the nations. Fortunately, we are already equipping for action. The League of Red Cross Societies, the International Health Office, the Rockefeller Foundation, and others are laying the groundwork for coordinated world action.

Exact Measurements of the Cost of Disease

THE failure of many health appeals to the legislatures and to the public has been due to the lack of exact information of economic loss. We have estimates of the cost of disease to the state, but the cold facts are not always at hand.

The Metropolitan Life Insurance Company of-

fers the facts in their report of actual cash paid out during last year for deaths from various causes. The study of the report is recommended to all. Three-fourths of the forty-two million dollars paid out by the company on account of deaths go to pay for the havoc of ten diseases. The order of the most important of these is: tuberculosis, pneumonia, heart disease, accidents, cancer, Bright's disease, and cerebral hemorrhage.

If the public could feel the actual cost by paying it out of their pockets, we would doubtless make more intensive campaigns for the prevention of these diseases which are causing the loss.

The Practice of Individual Preventive Medicine

PREVENTIVE medicine usually connotes the eradication of a disease by improved methods of detection, preventing contagion, or segregation. Typhoid fever in 1900 was a common disease on the wards of any big general hospital; in 1921, thanks entirely to the work of those interested in preventive medicine, typhoid fever is a rare disease. So yellow fever and malaria have been studied and removed from the common plagues; now typhus fever is being investigated, the method of its transmission is understood, and very probably in the near future typhus fever will be a rare disease even in the spots where it now rages.

But all this ground work, when viewed from the angle of the average individual practitioner, partakes of the nature of a grand celebration in which he has no part. He reads his medical journals and knows what is going on: if he sees a point of individual prophylaxis which is a part of the major program, he readily does his share; but the average practitioner of medicine is not an active contributor to the program of preventive medicine. We believe that he can be a much more active contributor to the program, if the selections were made more "popular" and less symphonic.

We suggest for the program makers philosophical and imaginative inspiration as well as scientific. The laws of cause and effect in disease must be turned backward and applied to the individual. The lessons learned from studying late effects of disease should be analyzed and then applied to the prevention of the disease in the individual. Of course, this is common enough practice and already has shown results. But we believe that too strenuous a logic has often been used, with the result that the individual has been neglected for the disease—a point Mackenzie has emphasized frequently. The importance of scientific

imagination has been overlooked in the application of hard and fast rules of scientific inquiry.

Perhaps we can make our point clear by a few examples: Taking, for instance, that large group of patients who are seen especially in office practice and who have the symptoms grouped, for want of a better name, under the term "essential hypertension." With these patients it not infrequently happens that a most careful study of possible focal infection is without results. Certainly in some focal infections symptoms are cleared up and the patient becomes better; but in a large percentage of these patients, even if infections are found, their removal does not by any means have the desired effect on the symptoms.

Since it is hardly possible for any illness to exist without a cause, it must be evident that some cause other than a focal infection may have been the active contributing element. To find this cause needs the exercise of scientific imagination as well as pure science. The patient will admit that some time during his life he was sick. Perhaps he was subject to colds or sore throats, or an over-indulgence in tobacco or alcohol may be discovered. The thought must occur that repeated attacks of a slight ailment may in the long run produce an evident disease, even though at the time of the attack no harmful result manifests itself.

The idea that this kind of reasoning, aided by the imagination, may be scientifically correct receives considerable support from a study of the influenza epidemic of recent years. The most outstanding clinical feature of the 1918-1919 wave was the observation that the heart apparently remained unaffected except in the fatal cases. It was so striking a feature of the disease that if myocardial insufficiency was found or even if the pulse became faster, the physician felt that that phase belonged to a complication or sequelum of the real disease. Yet, notwithstanding the apparent immunity of the heart, about eleven or twelve months after the epidemic, case after case of myocardial insufficiency developed in patients who had suffered from influenza. Post-influenzal myocarditis became a common affliction in the fall of 1919. It is obvious that the disease influenza had affected the myocardium in a large number of persons, even though these myocardial changes were not recognizable at the time they occurred.

This being true of influenza, we are justified in applying the same reasoning to acute follicular tonsillitis. We know the terrible triad of tonsillitis, arthritis, and endocarditis, so that we are aware of the potential dangers of a tonsillar infection in a certain number of patients. It must be true that attacks of acute follicular tonsillitis

may damage a heart muscle to an insufficient degree to be demonstrable by present day methods, but that the result of an accumulation of such slight damages may eventually be a real cardiac lesion. It is almost axiomatic to say that any disease which may cause heart muscle changes may also initiate arterial changes or renal changes unrecognizable until many years later, when the already weakened system has to bear the burden of increasing years and increasing effort.

When recognized, the damage is done. In this particular instance, the practice of preventive medicine might actually obviate many of the diseases of middle and later life now classified as of "obscure etiology." Were the possible cumulative effect of damages from repeated slight insults to the human body kept in mind, we practitioners would insist on a more vigorous convalescent treatment of even mild infections. Bridgman has already shown how much too short the ordinary convalescent period of a pneumonia patient is. The same thing is probably true of the convalescent period of any acute infection.

We might refer to the prophylactic importance of proper dietetic regulations and to the inherent dangers of periods of deficient food supply. In the succeeding number of *THE NATION'S HEALTH* attention will be called to the work of Blunt and Wang on vitamins. A period either in childhood or later life in which some essential accessory food factor may be lacking certainly produces definite symptoms. It is indeed possible that less glaring examples of the same deficiencies may be responsible for some of the ailments of later life.

The practice of preventive medicine in the individual case finds no better example than in the discussion of developed cardiac diseases. The history of cardiac patients depends to as great an extent on the social and economic status of the patient as on the condition of the heart itself. Hospital records show that the ward service will have many repeaters with heart disease. These repeated attacks of decompensation are preventable in most instances and, though the problem is not entirely individual, it is the function of preventive medicine so to handle the individual cardiac patient as to make it possible for him to carry on only the amount of work just under his minimum efficiency. Many such patients can be prevented from having recurrent attacks and also can lead healthful and useful lives if the period of convalescence is sufficiently prolonged.

It has long been recognized that the object of treatment of patients with pulmonary tuberculosis, especially those of the poorer class, is not only restoration to physical health, but also to economic efficiency. Simply to send a wage earner

away for six months' vacation means nothing: the practice of preventive medicine would aim to keep up this man's family unit and to restore him to a position where it would be possible for him to support a family and maintain his health at the same time. In surgery, again, the opportunities for individual prophylaxis occur almost continually. The man with flat feet or broken arches may have symptoms easy enough to relieve, but if he is not to become a burden to himself and the community, he must be prevented from having future troubles, the basic cause of which probably lies in the nature of his occupation.

In conclusion, it seems well worth while to call attention to the opportunities which lie at the door of each individual practising physician to do his share in the great program of preventive medicine. It is not necessary that he take part in anti-typhus or anti-typhoid campaigns. If he remembers that each patient whom he sees offers a problem of prevention and if he is willing to speculate a little concerning the past and future, he will have no difficulty in realizing his opportunities.

Announcement of Child Health Demonstration

ANNOUNCEMENT has been made through the Child Health Council that an appropriation of \$200,000 has been set aside for the purpose of developing in some typical American community of between 20,000 and 30,000 population conditions as nearly ideal as possible for the nurture of children from babyhood to adolescence.

That such a scheme has found financial and scientific backing through the six leading national health bodies is significant in itself of an awakened consciousness of community responsibility for the development of children into sturdy, happy, useful citizens. What it is possible to do in the way of making conditions favorable for the proper care of the children has heretofore been attempted only sporadically and spasmodically. No consistent program has ever been fully carried out. What is possible of accomplishment, therefore, can only be conjectured. It may safely be asserted that Nature has never been given a similar chance in a similar scope to show what she can do for her children. Artificial conditions hamper their growth and put inhibitions upon inherent physical and mental capacities that never find full play. Before we are willing to accept as inevitable the high percentage of handicaps prevalent in children of school age and in young adults, some such demonstration is in order.

The community for the demonstration is yet to be selected. Its choice should be the object of the keenest competitive effort on the part of all cities who are forward looking in community effort.

The committee which will recommend the town to be chosen for the experiment, consists of Dr. Richard A. Bolt, of Baltimore, general director of the American Child Hygiene Association; Miss Ella Phillips Crandall, of New York, formerly director of the National Organization for Public Health Nursing; Dr. Charles J. Hatfield, New York, director, National Tuberculosis Association; Owen R. Lovejoy, New York, general director, National Child Labor Committee; Miss Sally Lucas Jean, of New York, director, Child Health Organization; Dr. Haven Emerson, former health commissioner of New York, and Dr. Donald B. Armstrong, Framingham, Mass.

The direction of this novel health experiment will be under Clarence King, who is widely known in the field of research and the administration of health and social work. He holds degrees from the University of Wisconsin and Columbia University.

How Do American Cities Provide for Public Comfort?

A NATION-WIDE survey of public comfort stations just made by *Domestic Engineering* and published in a current issue brought replies from 120 cities each with a population of 25,000 or more. The question, among others was asked, how many cities had stations equipped for both men and women and what the buildings cost, how many were recently erected, and how many within the last twenty-five years. An analysis of the data showed that 67, or 56 per cent were provided with stations, totaling 173, an average of 2.6 to a city. Twenty-nine cities had one station; 18, 2; 5, 3; and one, 12. Thirty-one cities, or 26 per cent, had plans under consideration, while of the remaining 74 per cent, 42 cities, or 35 per cent, report that because of lack of funds, no comfort stations were planned. Fifty-three cities, or 44 per cent, were without any stations whatsoever, and 11 others stated that no progress is being made toward remedying the situation.

The usual method of support is taxation. Provision for ample public toilet facilities in any city does not need support by argument, but it is astonishing to observe the general lack of attention given to the situation. Several features must be incorporated in a modern station: it must be sanitary, well lighted, and properly ventilated. Asheville, N. C., recently completed an under-

ground structure at a cost of \$28,000 which sets an example in arrangement and equipment that might well be followed by every city in the United States.

Possibly the first public convenience of any kind was established by New York City May, 1869, in Astor Place, as a result of some twelve years fight by sanitarians. According to our present standards it was poorly placed, crudely constructed, and badly kept. In 1896 there was a movement for the erection of convenience kiosks, Paris style, since which time 1,900 various types of constructions have been tried out. During the years 1919, 1920, and to date in 1921, 27 buildings have been erected in various sections of the country. Portland, Ore., erected a building costing \$47,000, Minneapolis, Minn., \$37,000, and Allentown, Pa., \$42,000.

Those cities not maintaining stations assign various reasons for their laxity: ten pointed out a lack of funds, some the lack of suitable sites. The fact remains, however, that public comfort stations are greatly needed and are an asset to every community.

William Thompson Sedgwick Pioneer in Health Work*

IN THE death of William Thompson Sedgwick, on January 25, America has lost her most distinguished educational leader in the field of public health.

Sedgwick graduated from Yale in 1877 and took up the study of medicine, but the methods of medical education which then prevailed did not enlist his interest. He went to Johns Hopkins in 1879 (Ph.D. 1881), and under the influence of Martin became a biologist and perhaps the leading exponent in this country of the broad and fundamental viewpoint which Huxley had impressed upon this science, a viewpoint which was the basis for all of Sedgwick's later thinking. In 1883 he was called to the Institute of Technology, to whose service he gave himself with unsparing devotion for thirty-seven years. His special bent was at first toward physiology, and to the end of his life the problems of personal hygiene had a peculiar charm for him. In the earlier eighties, however, the new science of bacteriology was just beginning to open alluring vistas of knowledge, and of usefulness. Sedgwick at once grasped the significance of the work of Pasteur and Koch and, when the Massachusetts State Board of Health was reorganized in 1888, he was appointed biologist to the Board and became a pioneer in the application of bacteriology and microscopy to the

*This tribute to Professor Sedgwick was written by Dr. C.-E. A. Winslow in Geneva, Switzerland, and forwarded for publication in THE NATION'S HEALTH.

sanitary and environmental side of public health. He and his colleagues in Massachusetts did for this branch of bacteriology what Welch accomplished for its pathological bearings in Baltimore, and Prudden, Biggs, and Park for its diagnostic and serological aspects in New York. In the allied field of epidemiology, Sedgwick's studies of water and milk epidemics were of the first importance.

It is perhaps fortunate that the medical curriculum of 1878 failed to hold the interest of Sedgwick, for as events transpired he was able to perform a function of peculiar importance—to create practically a new profession of public health, outside the field of medicine itself. Before 1890, what sanitation existed was chiefly a by-product of medicine, as is still largely the case in Europe at the present day. Under Sedgwick's influence, however, the rôles of the public health engineer and the public health bacteriologist were definitely made clear, and even in general administrative positions men soundly trained in public health, but without the medical degree, have held their own with distinction. This phase of Sedgwick's life work found a logical development in the plan which he put forward in an address at the University of Cincinnati, only a few months before his death, for a reorganization of the medical curriculum so that, after the first two common years of preclinical study, the student might choose between two alternative junior and senior courses, one leading to the Doctorate in Medicine and the other to the Doctorate in Public Health. Although the expansion of administrative public health work to include dispensary organization and hospital management is likely to render the purely medical aspects of the subject of increasing importance, it is now clearly recognized that the medical curriculum must be supplemented, if not in part replaced, by specific training in public health in order to equip for adequate public service, a result which is largely due to the initiative of Sedgwick, and his colleagues and pupils at the Institute of Technology.

Sedgwick was far more than a biologist and a sanitarian. He was a good citizen; and his counsel and his energies were always at the call of progressive civic movements. As a member of the Advisory Board of the United States Public Health Service, of the International Health Board, and of the Public Health Council of Massachusetts, as president of the Board of Trustees of the Sharon Sanatorium, as trustee of Simmons College, as chairman of the Board of Trustees of the Pauper Institutions of Boston, as a leader in the fight for Civil Service Reform, and as curator of Lowell Institute, he set an example of fruitful service to the city and state and nation. On the

very evening of his sudden death, he attended a meeting in the interests of a state university.

Above all, however, Sedgwick was a teacher. Through his many addresses, which were always informing and distinguished, as well as singularly effective from a popular standpoint, and through his "Principles of Sanitary Science," which many academic generations have found of absorbing interest, he reached an extraordinarily wide public. Yet in the end the most far-reaching influence of his beneficent life will probably be found in the relation he bore to the group of students who came, in the laboratories of the Institute, under his direct and intimate guidance. From Jordan and Whipple, and Mathews and Calkins, down through the later years, Sedgwick's pupils have gone out as teachers and investigators and public servants, and there is scarcely an important step in the progress of public health during the last three decades in which they have not played a notable part.

Sedgwick brought to his task as a teacher keen powers of observation and a tireless curiosity. He had a broad background of culture, based both on reading and on travel. He saw every phenomenon in its relation to the past and the future, and to the underlying philosophy of life; and his own philosophy was rooted in a calm and serene acceptance of the universe and its fundamental righteousness. He knew his students intimately, knew their faults and their limitations, but fostered their latent possibilities with an unflinching optimism. He was more than a teacher; he was in actual truth a second father to hundreds of young men. The supreme things that he taught them, by example rather than by precept, were the love of exact truth and the spirit of self-forgetful service; and the torch which he kindled will be transferred by reverent hands to future generations.

C.-E. A. WINSLOW.

Baths as They Affect Community Health and Morals

A PROMINENT social worker in Chicago some days ago made the statement that in relieving unfavorable conditions as affecting family life, physically and financially, the chief factor to be considered is the housing condition. When an agency is able to give a family room enough—with privacy and adequate sanitary provision—self-esteem returns and other questions largely take care of themselves thereafter. So potent a force is the matter of personal cleanliness, it may be axiomatically stated that "the washed" belong to the elect, and "the unwashed" to the common herd.

On another page of this issue the statement is

made that the "lot of the submerged tenth" is insupportable largely on account of the inadequacy of general sanitary provision in rooming houses; and again, in the discussion of the means of making dusty trades safe for the workers, comment is made that the chief advantage of exhaust systems over wet grinding is that it is cleaner and "more comfortable to the worker, and less likely to produce discontent among them." No single measure is more important for the comfort and self-respect of miners than provisions for "cleaning up" after their work, and in many industries the showers constitute a most important part of the equipment.

All of this has to do, however, with the hygiene of personal habits, of cleanliness rather than bathing as a factor in industrial hygiene. Some of the older psychologists held that, the preference for cleanliness being universal, it could be assumed that there is an instinct for cleanliness.

Without arguing for an instinct for cleanliness, it may be pertinent to observe that too often health programs go far afield in finding causes and remedies for social ills, becoming ineffectual through broad generalizations, when correction is simple and ready for application in concrete problems of ventilation, or plumbing, or illumination. Bathing, for instance, is a salutary habit which will become more popular when baths, public and private, are universal; it will not be considered a measure sufficiently used when the bath is employed merely for cleanliness, but the importance of the bath will have more attention as to its frequency, its duration, and its purposes when employed to promote rest and relaxation, for the benefit of its stimulation, and even for its therapeutic uses. From the "Bath-a-Day" campaign instituted by a contemporary magazine we take the assertion that it is not to be taken for granted that even among "the washed throng" people know enough about the value of the bath to get from it the fullest possible quota of benefit.

IT IS a matter to cause some concern that in most of the forty-two legislatures meeting this year a halt has been called in legislation dealing with the improvement of conditions affecting little children. At the same time, largely because of unfavorable industrial conditions, child labor has shown an increase during recent months.

Every one who is interested in securing a fair chance for the children should interest himself and learn the actual status of childhood in his own community and should stand back of constructive work for better schools, better school laws, and supervised work and play activities.

Reliable data on research in eight different departments, including juvenile courts, recreational life, child labor, schools, children on farms, health, administration of laws, and statistical research, may be had through the National Child Labor Committee. Intelligent public opinion must back the necessary legislation. The future lies with the children.

CAPTAIN F. L. BEALS, U. S. A., whose article on the health problems of the summer camp is printed herewith, is an authority on the subject. He is professor of military science and supervisor of physical education in the Chicago public high schools and the founder of Camp Roosevelt, the official summer camp of the boys from the Chicago high schools. He approaches the subject of camp sanitation and camp health from the standpoint of practical experience and his opinions are worthy of special consideration.

A NEWS announcement from New York City states that according to the report of the chief medical examiner of the city, suicide among married males and females is nearly twice as great as that among single people. Much comment will be produced by this item, but until all the factors are weighed no conclusion can be drawn. For instance, the age factor is important. The married people have a much higher average age and consequently there is much more likelihood of mental breakdown. In the meantime the paragraph writers of the newspapers will have fun with the infelicities of married life.

THE official census of Japanese recently completed does not seem to bear out the statements of the great increase in the population of the country. The total population of Japan proper was found to be 55,961,140 and of the empire 77,005,510. The figures for the Japanese was somewhat under the official estimates of 1918, due probably to the fact that the census was the first to be conducted with modern census taking methods.

Vital statistics recently compiled are not reassuring to the Japanese. The death rate for males in 1918 was 26.93 per thousand, and of females 26.73 per thousand, figures which are far in excess of Western countries for the same year. The births for that year exceeded the deaths by only 300,000.

An alarming fact is also disclosed by the statistics published, in that the divorce rate was 112.8 per thousand marriages.

Health Problems of Women in Industry

**Expert Inquiry in this Field Must Precede a
Statement of the Case of the Woman in Industry**

BY MARY ANDERSON, DIRECTOR, WOMEN'S BUREAU, UNITED STATES DEPARTMENT OF LABOR, WASHINGTON, D. C.

PRACTICALLY speaking, the entire program for the regulation of hours, wages, and conditions of work for women in industry is based upon the power of the state to protect health. It is the recognition by the courts of the special significance to general welfare of the health of women combined with the more serious effect upon women than upon men of long hours, low wages, and unhealthy working conditions, which has resulted in the upholding of laws regulating such conditions. With the legal sanction for such regulation once given, legislation of one sort or another affecting conditions under which women may be employed has been put on the statute books of every state in the Union except New Mexico. These laws vary in the different states, of course, ranging all the way from a careful regulation of hours and wages and a very definite supervision and control of working conditions in states such as Oregon, California, and the District of Columbia, to the requirement simply of seats for women workers in certain occupations in Alabama, Florida, and West Virginia.

Standardization is Essential

In spite of the fact that the theory justifying the power of the state to make these regulations has been so generally accepted, the regulations enforced have varied to such an extent that no two states have established the same standards. For this

reason one of the earliest tasks undertaken by the Women's Bureau when it was first organized was to formulate definite standards for the employment of women in industry, which could serve as a guide to the many different groups who were working for the better protection of wage earning women.

The standards thus formulated cover conditions only in a general

America will be as strong as her women.

way, but they are the fundamentals which apply to all industries and all occupations. Qualifications and elaborations may have to be instituted to meet special cases and peculiar conditions, but the fundamental standards necessary to insure health and efficiency will not be altered. Briefly stated, these standards for women in industry which constitute the pro-

gram and the creed of the Women's Bureau are:

The eight-hour day.

Saturday half-holiday.

No night work.

A living wage based on occupation and not on sex, with the minimum rate sufficient to cover the cost of living for dependents and not merely for the individual.

Good working conditions, including adequate washing facilities; adequate and sanitary toilet accommodations; dressing rooms, rest rooms, and lunch rooms; clean workrooms with carefully adjusted lighting, ventilation, and heating; plentiful and sanitary drinking facilities; chairs, machines and work tables adjusted so that the workers can either stand or sit at their work; carefully guarded machinery; elimination of the necessity for constant standing or other posture causing physical strain, repeated lifting of heavy weights or other abnormally fatiguing motions, and the operation of mechanical devices requiring undue strength; exposure to excessive cold, or to dust, fumes or other occupational poisons without adequate safeguards against disease.

Prohibition of employment of women in occupations involving the use of poisons which are proved to be more injurious to women than to men.

Prohibition of home work.

Establishment of systems of employment management.

Cooperation of workers in establishing standards.

In this group of standards there readily are found many recommendations which apply fully as strongly to men as to women. For instance, there is no indication that bad ventilation in a workshop is a more serious menace to women's health than to that of men, nor that it has any distinctive effect upon women. Insufficient ventilation will lower the efficiency and the ability to resist disease of both men and women, and it should be recognized as a problem for all employees, in all industries, under all conditions.

The prevention of glare by properly placing and shading lights is another working condition which is not particularly a woman's problem, but instead is a problem for all in industry.

Specially Applied to Women

In fact, very few, if any, of these recommended standards can be said to apply only to women, and the Women's Bureau does not advocate that they should be considered as applying only to women. The important thing about them is that they apply *especially* to women. For all conditions in industry bear particularly heavily on women, and therefore good working conditions, hours, and wages have a more important relation to their health. Long hours in the factory are not as serious for the man, who is through work when he leaves his job at night, as they are for the woman who has often several hours of housework to do after she gets home. The married woman in industry, who is forced to work because of economic necessity, brought about by her husband's death, incapacity or inability to earn an adequate wage for himself and his family, must usually take whatever job she can get, without too much question of wages or hours. But she is the one worker in all the group who most needs the protection of the law, for the care of her children and household will take many hours and much strength, and her health will suffer if hours of work are not limited.

Perhaps the greatest two health measures which industry can institute for all workers, but particularly for women who are not organized so that they can make their own demands, and who are massed in the low paid industries, are the eight-hour day and the payment of a living wage. It has already been pointed out how the long hours are a special hardship for women, but the low wage paid to the average woman

worker is an even greater menace to her health.

A recent investigation made by the Women's Bureau disclosed the fact that in the main industries in Kansas in 1919 and 1920, the median wage paid to women was \$11.95, with 20 per cent of the women earning an average weekly wage of less than nine dollars. The Ohio Council of Women and Children in Industry has found that 14 per cent of the women in that state were receiving in 1919 less than \$10 a week and 52 per cent less than \$15 a week. The Women's Bureau found that in 1920 half of the women employed in the industries of Atlanta, Ga., were receiving less than \$11.70 a week. Conditions such as those exist throughout the industries where women are employed and the standard of living which a wage of around \$12 a week must require should certainly be recognized as a

or father who has died or been incapacitated.

The Pin-Money Fallacy

With this great necessity upon them for an adequate wage, women must struggle constantly against the old "pin-money" fallacy. A man feels that wife and children or other dependents are something of a burden, but he is recognized as the breadwinner, or the potential breadwinner, for a family group, his wages are based accordingly, and his burden is lightened. A woman may, and often does, have an equally heavy burden of dependents, but this burden is not made lighter for her by the popular superstition that she is working to make a little extra money, and will soon get married and be on "easy street" for the rest of her life. The Women's Bureau hopes shortly to have comprehensive figures showing

New York State Lumber Jacks. One employer said he preferred women to men because women always carried two planks at once if they could possibly manage it.

condition which will sap the health and vitality of a large group of workers.

This is particularly true when the woman worker is recognized as a provider not only for herself but frequently for dependents as well. The responsibilities of the wage-earning woman and her contribution to the support of others, mother, father, sisters, brothers, husband, children, have not yet received full recognition from industry or from the general public. Yet every investigation which touches wage-earning women piles up the evidence that women are working more often than not to eke out some husband's or father's insufficient wage and make it adequate for the family needs, or to earn the wage which had formerly been earned by a husband

the extent of the responsibility for the support of others among wage-earning women. Even before this material is prepared, however, there is ample evidence that this responsibility is much greater and more universal than is generally supposed.

Aside from hours and wages and general working conditions, there are certain conditions in industry which need to be especially studied for their effects on the health of women so that proper regulations may be instituted for their control.

The very widespread use of the piece work system in industries where women are employed is a condition which is now challenging much attention. Nearly every manufacturer will say that he employs women most successfully on the repetitive pro-

cesses in his plant, the processes that require an infinite number of rapid repetitions of the same movement such as placing small bits of metal under a press and releasing the press so that the metal is cut or hammered into shape; feeding machines which place the caps on tin cans, which means putting one tin can after another in the same place as fast as the hands can move; wrapping and packing cigarettes; or running an electrically driven sewing machine which makes two thousand or more stitches a minute. Such occupations, which are paid for by the number of finished articles turned out, naturally are carried on at full speed, in some cases under conditions of machinery or kind of work which require very careful attention. The pathological effect on the nerves and health of a woman of this continued tension and activity has never been definitely determined. Any casual observer of women working at these processes will know, however, that they must have pathological significance. Indeed, when girl after girl in a group of cigarette packers is found to be afflicted with a constant jerking or rhythmic motion of her body which follows the motions she makes while at work, resulting in extreme fatigue and nervousness, it would seem that the effect of the speeding up of piece workers in some occupations was so obvious as to need but little research to stamp it as being a serious menace. There is great need for careful and full examination of the effects of this system in order that it may be properly controlled.

Posture at work is another subject which has received insufficient attention, although the need of some regulation has been more generally recognized. It is very common to find state laws requiring that seats be provided for women who are employed in industry, but there has as yet been no definite standard established of the kind of seat that should be required. An old box with a plank

some of the seats which are commonly found where women are employed. Many requests are made to the Women's Bureau by managers of factories for descriptions of the best type of factory chair for women, but so far no investigation of the subject has been complete enough to warrant a definite recommendation. The fundamentals of proper seating, the need for a back, footrest, rounded front to the seat, and individual adjustment, have been established, but there is still much which needs to be known from the medical end of the question before a complete seating "code" can be formulated.

Very little has been gathered of the effect upon women's health of continued standing or sitting. Standing, of course, has received more attention as its effects are more quickly noticed, but that sitting for eight, nine, or ten hours a day can in itself be harmful is a new idea to many employers as

This arrangement is a makeshift adjustment. No back rests or foot rests are provided.

done with apparently little medical knowledge or study of the subject, the legislation is haphazard and may result in unnecessarily restricting the employment of women.

In Ohio and Pennsylvania a woman may not lift a core and core box the combined weight of which is more than fifteen pounds. In New York women in the core rooms of foundries are prohibited from lifting more than twenty-five pounds. There is a very great difference between fifteen and twenty-five pounds, and it is obvious that if fifteen pounds is all that a woman can safely lift in Ohio and Pennsylvania, the women of New York are being permitted to endanger their health; while if twenty-five pounds is safe for a woman in New York to lift, the women of Pennsylvania and Ohio are being unnecessarily restricted in their work in core rooms.

There are so many ways in which a weight may be lifted,—up or down, continuously or occasionally, pushed or pulled,—and the way of doing it, whether with the arms or back, with a sudden effort which might wrench or strain, or with a careful coordination of all the muscles which can be brought into play, may vary so with each individual that the standard amount which can be lifted safely will be very difficult to arrive at. If any such restriction is to be imposed, it should be done only after a very careful examination of the effects of lifting and a very minute description of the surrounding conditions which would render the lifting of such a weight a menace to health. In this case, again, adequate testimony on the subject is totally lacking.

In addition to the more or less mechanical conditions such as seating and lifting which may affect the health of women, there is another and very broad field which research has

A study in posture. A precarious footing and an uncomfortable seat for women cutters in the shoe industry.

well as to the workers themselves. It is quite possible in the majority of cases to regulate the height of work table and chair so that a worker may either sit or stand conveniently at work, but before such a treatment of the problems of posture can become general, the need for it must be very strikingly illustrated by a definite account of the effect on a woman's health of too much standing and sitting.

An attempt has been made in several states to fix a standard weight which a woman may lift without harm to herself, but as this has been

·HAPPINESS·

No night work, but normal sleep for women workers.

nailed against it for a back, a high stool with no back and no footrest, a barrel, a wooden kitchen chair, are

hardly touched. This is the peculiar effect upon women of certain fumes and gases used in industrial processes. It has been established without doubt that the effect of lead poisoning incident to exposure to lead in the form of dust or fumes, has a much more serious effect upon women than upon men. It is known that lead poisoning in women may result in sterility or in children being born dead, or in more of their babies dying during the first year of their lives. Such results have not been found in the case of men who have suffered from lead poisoning, and, because of this knowledge, in some states women are legitimately barred from employment in occupations where the danger of contracting lead poisoning is great.

It was only a careful study of a large number of cases of lead poisoning among men and women over a considerable period which produced the evidence which established the fact of the heightened susceptibility of women and its definite effects upon them. Women are working in many other occupations in which they are exposed to poisonous fumes and dust, but no evidence is yet forthcoming to show to what extent these elements are particularly dangerous to them, and without such evidence there can be no just and wise regulation of their employment.

The present day is hearing a great cry that women should be given equal opportunity with men for all occupations in all industry, but even the

most ardent of these exponents of the new creed of feminists will pause before a presentation of the case for better protection of working women based on a scientific study of the effect on their health, and that of future generations, of exploitation, long hours, low wages, and improper working conditions. The women of today as well as their employers "come from Missouri." No sentimental or idealistic appeal will be sufficient for either of them now. They want facts, and if the facts are presented strongly and clearly they will get action. But the facts must be collected first, and the field is open and crying for attention from scientists and health experts as well as from industrial engineers.

Experiments in Control of Air Dustiness

By O. M. SPENCER, PAST ASSISTANT SURGEON (R), UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

THIS discussion will deal with the results of some recent studies, made by United States Public Health Service officers, of air conditions prevailing in certain occupations and having a tendency to excite or accelerate the development of tuberculosis.

It is commonly known that there are certain principal occupations creating air conditions that tend to produce characteristic fibroid changes in the lungs, commonly designated as pneumoconiosis, which changes predispose the worker to infection from the tubercle bacilli. I refer here to such trades as those followed by cutlery makers, filers, grinders, abrasive workers, polishers, buffers, manufacturers of jewelry, brass workers, finishers, sand blasters, saw filers, tool-makers, glass blowers, glass workers, cotton workers (because of mineral substances used in sizing), marble and stone quarry men, molders, potters, miners of copper, gold, silver, graphite, iron, lead, zinc, mica, phosphate, spar, and quicksilver. These trades are typical, and the list inserted here is not at all complete.

Air Purification Called For

We have become accustomed today to certain standard methods for air purification in industrial plants. These methods take the form of hoods, exhausts, and fume lines usually beginning at or near the work plane and following certain engineering specifications, exhausting at a place sufficiently remote and protected

to control the hazards arising from the occupation. In certain occupations where it has been thought that such fume lines could not be satisfactorily installed and operated, wet processes have been introduced. In point of origin, the wet process antedates the exhaust as a means for controlling dusty operations. To a large extent these two processes have given a sense of security to the operator and the operative.

States as governmental units, and, in some instances, municipal authorities, have endeavored to standardize such safety devices by fixing the size of the fume line, the number of branches that may enter a main without increasing the size of the main, the angle at which such branch pipes must enter the main pipes, the strength of the exhaust as determined by anemometer or U-tube readings, and like precautions. These regulations, occasionally enforced by factory inspection, have given an added sense of security to the hazardous occupations. The great question is, however: Is this sense of security fancied or real? Certain observations made by officers of the Public Health Service aroused a doubt as to the adequacy of these so-called protective devices and led to a comprehensive research.

All dust counts mentioned in this work were made from samples collected by the Palmer water-spray machine, and refer to the number of one-fourth standard unit dust particles per cubic foot of air, as classified

by Palmer,¹ and arranged according to size, from 1 to 10 microns. It was shown by Dr. McCrea, in the report of the Miners' Phthisis Prevention Committee, of Johannesburg, South Africa,² that the dust extracted from the lungs of deceased miners by acid oxidation consisted of particles from 12 microns to less than 1 or 2 microns in diameter. The majority of particles is found in the smaller sizes.

Two Types of Control

It has been the almost universal belief that, of the two main types of control of air dustiness, wet grinding is safer and has a smaller dust hazard than dry grinding under an exhaust system. This in some instances has been proved false by recent studies conducted by Winslow and Greenburg in an ax-grinding factory.³ In this plant the owners were worried by the dry grinding with an exhaust system and were satisfied with a wet-grinding process, and so sought advice as to a feasible plan for correcting the former.

Dust counts of samples were collected by the Palmer water-spray machine in the wet and dry grinding shops by Winslow and Greenburg, with the following results:

1. Palmer, G. T., Coleman, L. V., and Ward, H. C., A Study of Methods for Determining Air Dustiness: American Journal of Public Health, 1916, VI, p. 1049.

2. Miners' Phthisis Prevention Committee—General Report, Johannesburg, 1916.

3. Winslow, C.-E. A., and Greenburg, Leonard, A Study of the Dust Hazard in the Wet and Dry Grinding Shops of an Ax Factory: Public Health Reports, Oct. 8, 1920, XXXV, No. 41, pp. 2393-2401. Reprint No. 616.

WET-GRINDING SHOPS

Number of samples	Number of dust particles per cubic foot of air (One-fourth standard unit)		
	Minimum	Maximum	Average
32	870,000	50,000,000	15,800,000

DRY-GRINDING SHOPS WITH EXHAUST SYSTEM

Number of samples	Number of dust particles per cubic foot of air (One-fourth standard unit)		
	Minimum	Maximum	Average
10	51,500	400,000	154,500

These experiments not only showed that the wet grinding was hazardous and gave a false sense of security, but they also showed that the exhaust system in the dry-grinding plant was adequate.

Two important facts stand out as a result of this test: one is that wet grinding was not, here at least, a safe method; the other is that the methods of testing adopted in this test give an actual picture of the efficiency of the system of dust reduction installed.

A survey of another plant was made by Scientific Assistant Myron Bantrell,⁴ and dust samples from which counts were made were taken in various rooms of the plants. The counts were of one-fourth standard unit dust particles and ranged in number from 69,000 on the roof of building to 5,548,000 in the grinding room. The average number of particles in the grinding room was 2,841,000. These conditions prevailed notwithstanding the fact that the management complied with the state laws in every way in its wet-grinding process, using a special compound of oil and water.

What Constitutes Safety

This survey brings out the important fact that even a strict compliance with the present laws in regard to wet grinding does not always prevent a dust hazard, and that it is absolutely necessary to have some definite method of checking up the efficiency of dust-prevention devices after their installation.

On the other hand, dry grinding with an exhaust system also has dangers and shortcomings; for care and attention must be given to the size and location of the hoods, the angle of taper of the ducts, the angle at which the branch pipes enter the main pipe, the use and size of the

bends and elbows, the plugging and stoppage of the screens in the hoods, and, the most important factor, the suction maintained at the terminal hoods.

Using the popular U-tube method of testing the suction in the exhaust pipe, and the Palmer dust machine to count the dust particles in the air, Winslow, Greenburg, and Angermeyer⁵ made a special study in the polishing shops of a small-arms plant by making observations in pairs: first, under normal conditions, with the exhaust system working, a dust count was made; then the doors in the main exhaust ducts were opened between the fans and the hood, and after an interval of 5 to 10 minutes, the work process being continued, a second dust count was made.

The results of these experiments showed that a reduction in the suction head readings of the U-tubes is quickly followed by an increase in the air dustiness; and a tabulation of the suction head pressure and the number of dust particles in these experiments proved that there is a definite relation between the suction head in the exhaust and the dust in the air, provided there is no interference with the exhaust system between the point of the U-tube reading and the polishing wheels. And it is this possible defect in the arrangement of the hood with regard to slope, size, position, angle, and partial or total stoppage of the screen, that forces us to realize that the U-tube test is not always one of accuracy and reliability.

Not only do these experiments demonstrate this fact, but they demonstrate the fact that only by the actual dust count at the plane of work and of the atmosphere of the room could the efficiency of the exhaust system be checked or relied upon.

The air exhaust has certain advantages in sanitation, because the worker can not, by cutting off the fluid, convert the wet method into the dry method; there is no deflected spray in the dry method causing the clothes of the worker to become damp; hoods can be arranged in the dry method to catch any particles of dust liberated; the suction head at every grinding wheel can be tested in the dry method and a comparison of the amount of dust produced by each worker can be made, and in this way any defects in the separate hood and branch line can be located. There is

no stream of water or other liquid to be kept fixed on a certain point in the dry method. The dry method is cleaner, more comfortable for the workers, and less likely to produce discontentment among them.

The important point, however, in connection with the installation or maintenance of either the wet or the dry system, is that the supervision of its operation should guarantee efficient control of the dust caused by the process. This can best be accomplished by use of a dust sampling machine and a dust count.

Palmer, Coleman, and Ward recorded the following dust content of the air of the city streets and occupied space where no particular dust hazard exists:

Source of samples	Number of samples	Average total count
Outdoors — Balcony City College.....	3	153,000
Outdoors — Woolworth Building (street level, 10th floor and 58th floor)	3	71,000
Business office.....	2	150,000
Department store, basement	4	108,000

This and the previous counts made under varying conditions demonstrate a method whereby standards for dustiness in any or all processes may be established. Physical examinations of the exposed workers, as well as x-ray plates of the lungs, in an intensive study over a long period of time, to see if the standard adopted for certain processes prevents the fibroid changes in the lungs produced by pneumoconiosis, must yet be made before any tentative standards can be accepted as adequate. It is in this direction that future work in dustiness must be conducted in hazardous industries to make the workplaces safe for the employees. This applies not only to grinding and polishing and to wet and dry exhaust systems, as here mentioned, but to all occupations and processes where dust hazards exist.

It has been shown that the present methods used for removing dusts are subject to many faults and defects, and that it is only by an actual dust count at the plane of work and in the room or at the place where the process is being conducted that we can determine the efficiency of the system and the amount of protection that is afforded the worker; and that tentative standards of dustiness can be created, by making dust counts in any place and under any conditions desired, pending a study of living

5. Winslow, C.-E. A., Greenburg, L., and Angermeyer, H. C., Standards for Measuring the Efficiency of Exhaust System in Polishing Shops: Public Health Reports, March 7, 1919, XXXIV, No. 10, pp. 427-449. Reprint No. 500.

conditions to change the tentative to real standards.

The Needs Summarized

I believe that I have made clear the following needs in the study of the control of air dustiness:

(1) The necessity for establishing a "standard dust table" of the number of dust particles of a certain size permissible in all dust-creating or dust-hazardous processes and occupations.

(2) The necessity for checking the

efficiency of all dust-removing systems or devices at regular intervals by an actual dust count at the plane of work and in the workroom, which count must come within the limits prescribed by the "standard dust table" for that particular process.

If these two suggestions should be adopted and included in every State law for the control of air conditions in industries, the amount of pneumoconiosis would be unquestionably reduced, and the mortality from tuberculosis in dusty trades diminished.

If, in addition to the establishment of the "standard dust table" to routine procedures of factory hygiene, and regular testing of dust-removing devices in plants by actual dust count, intensive education of employees as to their constant danger of tuberculous infection at home and in the plant is carried out and workers come to realize the hazards to which they are subjected, we may expect to lower the present industrial mortality rate from tuberculosis to that of the ordinary death rate.

Labor Shows Constructive Initiative in Health

A Demonstration of What Unionism Has Accomplished in Health Conservation

By I. A. GALDSTON, M.D., EDUCATIONAL SUPERVISOR, JOINT BOARD OF SANITARY CONTROL, NEW YORK CITY

LABOR'S lack of constructive initiative and managerial power is the final and all sufficient justification of their stand given by those who oppose the proposed changes in our current economic relation which have as their aim to give labor a greater share in the control of industrial affairs. When, therefore, certain institutions are in the course of events created by labor to serve certain of its vital needs, it is incumbent upon those interested in the validity of the claims against labor, set forth above, to examine into the nature and operations of such institutions and note the extent, if any, to which these refute the charges. Especially is this the case when such

institutions are not in duplication of ones established and operated by non-labor groups, but, quite the contrary, are innovations and pioneer organizations. The Union Health Center of the International Ladies' Garment Workers' Union is just such an institution.

Care for the Middle Class

During the agitation of last year, centering about compulsory health insurance, one point was brought to light which could not be refuted, and which had to be admitted even by the most bitter opponents of the proposed health legislation. This point dealt with the inadequate and incompetent medical attention which was afforded

to those with but a moderate income. As stated by the documents dealing with this question, only the very poor and the very wealthy receive sufficient and competent medical attention; the wealthy by paying the large fees charged by specialists, and the very poor by visiting the various hospitals and dispensaries in which the very same specialists are visiting and consultant physicians. The large middle group must do without such medical attention, because its members cannot afford the large fees charged by specialists, and because they will not suffer the inconveniences and implied poverty of a dispensary visit. This large group of our citizenry visits the doctor only when self-medication or the trust in things righting themselves avail no relief, and even then it is not always that they consult the most competent and most conscientious practitioners. It is a common experience of the physicians of the Union Health Center to have workers bring to the clinic series of x-ray plates for which sums varying from twenty-five to fifty dollars have been charged, and which have neither value nor meaning to the workers. So, too, many a worker, driven to distraction by some condition, the neglect of which has converted it from the simple matter it was, to the serious condition which it later becomes, falls victim to some unprincipled practitioner who exploits him to the utmost.

Of this large group of neglected cases the shop worker constitutes by far the greatest portion, and in addition to the other disabilities, he suf-

The waiting room in the Dental Department, the conference room in the foreground.

fers the handicap of being tied down to his job in a manner unknown to the office and non-shop worker, and with him, therefore, the problem is correspondingly more serious.

These conditions have prevailed for a long time, and have been long the common knowledge of those in the field of public health. Certain attempts, it must be stated, have been made to remedy the condition, but to date no competent solution has been developed. In Boston there is a co-operative clinic which has operated for several years, proving quite a success. In New York, during the past year, two attempts were made to establish such clinics, one at Mount Sinai Hospital, and one at St. Vincent's Hospital, but for reasons which cannot be entered into here, both failed. While these unsuccessful attempts were being made by social organizations, having at their command almost unlimited resources, and counting among those enlisted in their cause certain of our most competent leaders in the medical and social spheres, five locals from the International Ladies' Garment Workers' Union, numbering in membership sixty thousand, determined to try their own hand at solving that portion of this health problem which confronted them. They voted the sum of \$55,000, for erecting and equipping a Union Health Center to serve as a department of health, a hospital, and clinic to the 85,000 members of the Union. Dr. George M. Price, the director of the Joint Board of Sanitary Control, was placed in charge of the work and within five months the Union Health Center opened its doors to the full membership of the

Union. In the process of construction more money was required and the original sum was augmented by an additional \$45,000 making an approximate total investment of \$100,000.

The Union Health Center, which stands on Seventeenth street opposite the Washington Irving High School, in addition to being the home of the Joint Board of Sanitary Control houses a Medical Division, a Dental Division, and an Educational Division. The Medical Division which, exclusive of the auditorium, takes up the entire ground floor, has daily clinics for general examination and treatment, as well as clinics in seven specialties. In addition, there are an operating room for minor surgery, an

x-ray room equipped to take any type of x-ray pictures, and a laboratory. The Dental Division occupies the second floor save for a conference room. Here there are to be found eight dental chairs of the most modern type, a dental x-ray room, an instrument room, and a dental laboratory. The Educational Division, which is part of the Joint Board of Sanitary Control, is with that organization on the third floor.

Large Numbers Served

That the membership at large is appreciative of the Health Center can be seen from the large numbers that take advantage of its facilities. During the month of December the Dental Department treated 1,142 members, and the Medical Department, 560. Their confidence in it and its staff is of a degree seldom enjoyed by the private physician, for they reason that the Union Health Center and its staff are their own, and they can impute no ulterior or selfish motives to its practices.

In addition to the organization of the Union Health Center which is designed to give the worker the very best that his money can purchase and which seeks to avoid the dispensary atmosphere with all its austerity and accentuated assepsis, its operation is such that when a worker joins the Union he is required to undergo a complete physical examination. He is passed upon, and graded in accordance with his health status. Where treatment is required, such is advised and administered. From the very day he joins the Union, his relations with the Union Health Center are organic

The Clinic includes a fully equipped operating room ready at all times for minor surgical work.

Health exhibits and health lectures in the auditorium help to make effectual the other phases of the service.

and intimate. He, and the immediate members of his family are entitled not only to examination and treatment, but they may come for advice as well, and the value of the last can be appreciated only by those who have seen the helplessness of a worker when sickness or accident comes upon him and his family. Whatever possible is done for him in the Health Center, and, when hospital and surgical treatments are required, proper arrangements are made for him.

All of the medical and dental work is charged for on a cost basis. Never the least implication of charity enters into any transaction, and those professionally associated with the clinic receive remuneration for their services which, while not equal to value received, taking all factors into consideration, still is up to the standard rates.

Past Experimental Stage

The Union Health Center has been functioning for three months. During this period it has undergone a considerable modification, but it has served to realize at least a fraction of its possibilities. There is still a health school to be developed for the workers in which classes in the Union Health Center will be taught disease prevention; a life preservation and prolongation service is to be created, with annual physical examinations at an initial charge of five dollars, and a charge of three dollars for subsequent examinations; then there remain the possibilities of co-operation with the various other labor groups. Already complete arrangements have been made by the Center for cooperation with some

sixty physicians, to guard the health and render medical services to the members of the Amalgamated Clothing Workers Union, now in the midst of a strike.

There are great possibilities for the Union Health Center, whose value time will demonstrate, but even as it stands at present, the Union Health Center is a valid defense of labor against the charges of lack of initiative and managerial powers, and a challenge by achievement to organized society on the problem of health and life conservation. Further, it is a vivid and convincing demonstration of the truth that in health matters, as in economics, the salvation of the workers depends upon the workers themselves.

The Dental Department is made up of six such units as this, together with an x-ray room, an instrument room, and a dental laboratory.

Slow or Chronic Poisoning by Illuminating Gas

The *Therapeutic Gazette*, March, 1921, comments on a paper by Dr. Wilmer, of Washington, before the Section on Ophthalmology of the College of Physicians, Philadelphia, relating to the effect of slow or chronic illuminating gas poisoning upon vision. Dr. Wilmer points out that it is not always illuminating gas, but also gas from furnace flues and range flues in such small quantities as not to be noticed by the inhabitants of the house but in a sufficient amount over a considerable period of time to produce very definite results. Carbon monoxid is a dominant factor. The changes in the body produced from exposure day after day for weeks at a time are little known, but the question of gas as causative factor can be more carefully investigated.

Measures to Control Miners' Nystagmus

The *American Journal of Public Health*, January, 1921, outlines briefly an article of Sheffield's which states that miners' nystagmus is the most prevalent occupational disease in Great Britain, and that there seems to be a standstill in the matter of its elimination. Dr. E. R. Hayhurst in commenting upon this states that in America there is very little evidence of this disorder and attributes its absence to the fact that American soft coal mines are not actually gassy to a dangerous degree, hence miners are not obliged to work under the poor illumination afforded by the safety lamps required by law in Great Britain.

In the same issue there is a brief extract on eye strain and motion picture theaters, summarizing the investigations of the committee of British ophthalmologists, the Illuminating Engineering Society, and the Physiological Society. Among the various points considered are: proximity and position of seats in relation to the picture, instability of projecting apparatus, faulty manipulation, and brightness of the pictures.

Nursing for Trade Unions

The Cooperative Health and Nursing Service, sponsored by St. Paul's Trade Unions, sent its first nurse into district work February 1. The funds for the organization were raised by unions in the Trade and Labor Assembly. This is possibly the first nursing service initiated by a labor union.

Health in Industry and Efficient Production

To Reach the People and Educate Them in Means of Prevention is Our Problem

By S. DANA HUBBARD, M.D., SUPERINTENDENT, DIVISION INDUSTRIAL HYGIENE, DEPARTMENT OF HEALTH,
NEW YORK CITY

STATISTICS regarding health in industry are replete with interesting correlating facts. From the United States Department of Labor we learn that there are about forty million people in this country engaged in industry,—people who work for a living in factories, shops, offices, and mercantile establishments.

Of this army of workmen and women there are about 750,000 who sustain accidents which disable them for a period of more than four weeks' duration annually. There are about 22,500 industrial workers killed each year. There are between 15,000 and 18,000 who suffer permanent disability each year. The economic waste from this source alone means the loss of working time of over 60,000 laborers, or 18,000,000 work days a year.

Sickness Exact's Toll

Sickness in industry likewise exacts a heavy toll. We are informed from the same source that the average worker loses from illness about nine days a year. This means a loss of one million workers a year, or 360,000,000 days a year, which, estimated at an average daily wage, means a stupendous amount which is lost, when computed in dollars and cents, and much of it is preventable.

Add to this loss, the expenses of sickness, medicines, physicians' and nurses' services, sundry expenses plus the loss of production, and we have an amount which is staggering. There is therefore no greater problem before our country than that of caring properly for those industrially employed. This is further demanded from a public health policy because to reduce death rates we must attack those conditions which are destroying our producers.

A study of a twenty year experience in mortality statistics in New York City shows that, while the general death rate has been reduced from 20.57 per 1,000 population to 12.39—which means a saving of practically eight lives to each one thousand of our population. This has been accomplished from a reduction of child life under five years, which had a rate of 64.6, but is today but 24.7, and in the reduction of infant mortality—children under one year—from 192 to 82—but with it we find the middle aged are more rapidly passing away. It is therefore necessary to take steps to reduce the causes of death of this middle aged group.

Cancer is on the increase; Bright's disease is on the increase; heart disease is on the increase; and these are

the diseases incident to middle life.

To rear a family costs money. To train a workman costs money. Various estimates have been given regarding these two conditions, but what is the use of preparing offspring to take the places of parents when as they are prepared, they are stricken either by accident or illness and taken off? This, therefore, is the theme that is now before us.

In our estimation, much of this industrial sickness is wholly preventable and to reach the people and educate them in means of prevention is our problem. There are many individuals who utterly disregard regulation, but the intelligent and the anxious to learn appreciate that health regulation is the putting into practice something which is of some good to all.

The prevention of accidents and of occupational diseases in a number of industrial establishments has fully demonstrated that many accidents and much sickness can be materially reduced. The use of safety appliances and educational propaganda against these conditions have cost considerable money, but it has been spent in a cause well worth while if one may judge of the results.

Injuries and disease, however, in

Every possible care for the comfort of workers is provided by the manufacturing concern which houses this men's club. It is no mere coincidence that the labor turnover here is the lowest we have observed, proving the value of good environment.

Employees are entertained during lunch hours by music in this very hygienic and attractive eating room. The monotony of their tasks is relieved in other ways. Recreation is provided to effect a proper balance between work and play.

many instances, are contracted while the worker is away from his place of business—in the streets, in places of assembly, in the home, and in recreational places. The fatalities and injuries from automobile accidents are appalling. Disease, especially communicable, is often contracted in these latter places and taken into the shop and there spread to many workers because, either the sufferer was indifferent to the health of others, or else he was uninformed as to the danger and the need of care. Conspicuous in this regard was the epidemic of influenza. Illness of this character is responsible for an enormous wastage of time, money, and health. A broad vision with regard to our public health industrial hygiene program, within and without industry, is needed to approximate health ideals. The unexpected and extraordinary success of the division of industrial hygiene, considering the compara-

given a health foundation that will enable his physique to respond to the demands of the future job, whatever it may be. The physically ill are handicapped and cannot compete with others on an equal basis in industry. Inadequate medical supervision has been responsible for an appalling number of permanently handicapped individuals. Preventive medicine is concerned in the careful study of each individual in order to detect physical defects in their incipency. It is shortsightedness to seek medical aid only when ill. In industry it is shortsightedness to try and operate a plant without medical sanitary supervision.

It is likewise a grave error to hire cheap untrained doctors and nurses, who are already responsible for too many permanently disabled workmen. This statement may be verified by many State Industrial Compensation Boards. Many good medical men and trained nurses are seeking this par-

haps the most wonderful of their architectural creations were the splendid baths handed down by them to modern times. This may have been incident to the propaganda of that period whose record in stone is worthy of passing on to succeeding generations. In the Museum of Art in New York is an elegantly carved solid stone bath tub, probably Agrippa's of Caesar's time (27 B. C.).

We are informed by our Jewish friends that it was due to the teaching of the Bible that cleanliness in many of the tribes was practiced. Many of the old churches of former times had provision for bathing accommodations for weary pilgrims which carries a suggestion that might not be amiss in some of our modern sanctuaries. The church of today must give its stamp of approval to modern sanitation and aid in this necessary and helpful work. The chief reason for seeking this support is that a doctor, nurse, or public health official may advise methods for maintaining health but unless these opinions are endorsed and facilities afforded for conveniently carrying them into effect the advice is not followed.

There is an economic side to sanitation and this is particularly pertinent when it is applied to industry. Employers must take the lead and those who have already done so have made great progress toward improving working conditions, which has been reflected in better health of the employed with attendant increase in output without additional expense. If we reflect but for a moment, it will be apparent how much workmen are affected in their efficiency by their habits, by their environment as well as by their health.

Architects in designing and erecting modern factories are more appreciative than ever before of the necessity of carefully considering the demands of sanitation in these structures.

Laws Do Not Govern Habits

The laws regarding sanitation in its various features provides suitable regulations but it is impossible to regulate the habits of people by simply putting regulations on the statute books. It is the experience of the field inspector that human beings, in many instances, rebel against preventive regulations until they know the meaning of these well intentioned statutes. In many instances the builder provides and employer operates clean and sanitary shops but the ignorance, carelessness, and at times

Impossible conditions found in the home of a well paid foreman in whose family sickness had overworked the wife to the neglect of household duties.

In rather unfavorable quarters this housewife, with the aid of the industrial inspector, has arranged neat and sanitary provision of the necessary comfort.

tively short existence of this work, is a most striking example of this need.

Industry is losing many future workmen by neglect of the coming generation, yet much in New York City is being done for the workman and his family. Prenatal clinics and infant welfare clinics have done well, but there is still much that is left undone by lack of appreciation or lack of knowledge of this undertaking. These clinics have demonstrated their need and their remarkable effect is chronicled in the health statistics herein cited. In fact, it might be safely asserted that it is only through these splendid agencies and the cooperation of the public that our death rate of early life can be kept low.

The pre-school child demands medical and nursing consideration because only by proper and adequate care can physical development and muscular training be perfected and the child fitted first, for the school and, second,

ticular field of endeavor but the poor payment offered for this character of service by employers in industry will not elevate the standard of medical service. Prevention therefore consists in being prepared.

Indifference Imperils Life

The student of industrial sanitation is staggered by the indifference displayed by both worker and employer to many known facts of medicine which imperil the lives and health of those engaged in industrial employment, many of these also are a distinct menace to the health of the home and to public health.

To many, the word "sanitation" may be a new term, but under the term "cleanliness" we can trace sanitation back to the time of Moses, the most perfect code of health laws extant being found in Leviticus.

One of the chief delights of the Romans was bathing and so high did these people regard bathing that per-

contempt of the worker, set at naught the well laid plans.

We are as much concerned with old structures as with the new, because light, heat, fresh air, and toilet facilities may be furnished as required, these are mostly dependent upon the worker for comfortable operation, yet, while windows may be sufficient for affording plenty of fresh wholesome air for proper ventilation, it is not obtained because either some worker is dressed too thin or another may be afraid of taking cold. It is not unusual to find frequent complaints, one workman wants the windows raised and another does not; one raises the windows and another lowers them. How then can proper ventilation be secured?

Similar criticism holds about toilets, rest rooms, and places set apart for lunch or recreational activities. Have you ever visited a factory lunch room after it has just been used by a number of employees? If not, do so and see for yourself these very unpleasant conditions. What is done here is repeated in numberless ways? Public halls, public comfort stations, streets, parks and amusement places afford abundant evidence of the indifference of people generally to neatness, tidiness, and cleanliness. Have you ever lived next to a vacant lot? Have you observed our public parks after a holiday? These furnish abundant and shocking evidence of an utter disregard for public sanitation.

General Cleanliness

Nothing gives to the eye such a comfortable impression on a visit to a place of employment than the observation that everything is neat, clean, and orderly. Weeds, litter, piles of rubbish, broken fences, and dilapidated weather-beaten structures create a mental impression distinctly opposite to that which is felt when we visit a shop or factory and find the walks well laid out, the grass on the lawn green and well cut, the stocks of different materials stored in orderly fashion, and the buildings and their enclosures kept in the neat, clean and tidy manner that a good housekeeper would keep the home.

Close the eye to the outward appearance and go within, almost instantly it is possible to surmise the character of the business performed. Let the shop show in its best dress. Let the employers interest themselves and the employed will react like the heavy duty engine, which works carefully, accurately and steadily. Are the aisles clear and lighted, day and night? Are the drinking places in

order? Are the stairs clean and safe? If so, one may safely conclude that there is efficient management within and that those industrially employed are making good.

Probably it is a safe assertion to make, that nothing is so generally neglected in factories as general house cleaning. This is unfortunate as it is not only unhealthy but has a direct influence on morale and this in turn on industrial efficiency. Industrial managers that are wide awake are appreciating the economic value resulting from the proper cleaning of a shop or factory. Clean stairways, ceilings, walls, floors, lighting fixtures, windows, and machinery have a distinct economic as well as health value.

Under the broad term of general cleanliness it might be mentioned that nothing is more essential to efficiency of operator and output than fresh air, few things cost less and yet it is diffi-

Ten individuals, all apparently healthy, work in this basement junk shop, which is a distinct menace, both fire and health, to these workers and to the factory above.

cult to obtain uniformly in our homes, shops and factories.

In establishments where dust is created it is most essential to both health and safety that the particles flying about are properly and promptly removed from the atmosphere; in fact, it might be here stated that the prime essential of shop operation is the prevention of the contamination of the breathing air from dust. To obtain efficient operation in any plant careful consideration must be given constantly to good light and pure air. It is specially necessary that the air be free from poisonous vapors and irritating dust.

A most frequent and general offender against the laws of sanitation is defective lighting and improper placed lights. To do good work one must have not only adequate but properly placed lights and these lights must be looked after as domestic care is essential to full light capacity. To make lights efficient

they must be kept clean. Cleanliness and light are interdependent. Dust allowed to collect on glass protectors, on electric light globes, on reflectors together with dirt darkened ceilings reduces most materially the volume of light and by reason of using unnecessarily dimmed lights more current is consumed, because the additional amount of light required is furnished by using a larger number of lights. Reflectors dimmed by dirt cut down the efficiency of lights most materially and it would be but the work of a moment to have the globe and reflector wiped with an ammonia dampened cloth previous to use. The time of the employee taken to do this would more than repay for the time occupied.

Dark, dusty, dirty places of employment have a depressing effect on cheerfulness and very materially lower the morale of the operating staff which directly affects output.

Keep the Air Clean

Old fashioned dusting and dry sweeping are dangerous, as it scatters the germ laden dirt and contaminates the breathing atmosphere. The proper removal of this dirt and dust may be easily and quickly done with a vacuum cleaner, many of which are finding their way not only into the homes of our people but in our shops. It is important that the dirt collected by this method should not be thrown away but destroyed by promptly burning as in many instances it is germ laden. An instance of the danger of this may be cited in the horse hair industry. Here the raw product—imported horse hair—which is often used to make brushes, is often contaminated with dirt and this dirt is infected with the seed of a most fatal disease, anthrax. A number of workers have contracted this fatal disease in this territory from this source. If the buyers of brushes appreciated this menace, it is easy to conceive what would occur to the brush trade; a buyer's strike, which would not only close shops but throw many persons out of employment. It is therefore most necessary that every factory carefully perform its house cleaning service.

Investigation of many of our places of industry reveals the interesting fact that very many of these are cleaned by the most primitive of house cleaning methods, straw brooms and feather dusters being used, while some shops are cleaned only when the disorder is so acute as actually to interfere with work.

Industry should be up to the minute

and apply methods known to be not only efficient and economical but safe. While we endorse the vacuum cleaner and exhaust system, yet we feel that more important is the efficient removal and disposition of all rubbish, sweepings, garbage, and trash of whatever nature. This is in the interest of health and safety. Fire-proof receptacles should be furnished and used. Employees may be persuaded to use the proper receptacle, only by example, education and careful supervision.

One of the best ways to educate in a large plant is to have a house paper, and a bulletin board at entrances. Interesting personal facts should be placed before the workmen and reiterated in different form repeatedly until nuisances are eliminated.

Visits to many of our factories furnishes evidence that a number of our managers are concerning themselves with the outward and inward appearance of their shops. This is a good sign. On a recent visit to one large establishment which was "spick and span" regarding cleanliness and orderliness, was the following sign printed on each stair riser of the whole seven floors. "Spitting Forbidden. Anyone detected violating this rule will be instantly dismissed." The management informed us that the signs in question had been put on nearly five years previously, that there had not been a single dismissal, and the place was neat and clean with no visible evidence anywhere of any expectoration. Cuspidors are a necessary nuisance in many instances and the presence of these will prevent spitting promiscuously on floors, stairways, and in other places.

House-Cleaning Methods

The proper cleaning of these articles is often a problem with the management, yet many institutions solve this very easily, by using newspapers and factory waste which are easily destroyed in the furnace. A good method is to have a shallow, wide box, and paper neatly folded with overlaps, like an inverted baker's cap placed therein. This protects the box frame, collects the spittal, and is sufficiently large so that however poor may be the marksman he will strike the paper, and never the floor near the cuspidor. When it is considered that nearly one in every seven persons have some form of tuberculosis, and that during the prevalence of respiratory diseases—colds, influenza, bronchitis, etc.—this menace is greater, spittle is a great hazard to

health in factories. The management should never permit one of these utensils to be neglected. Each day the old paper should be collected in a metal container, a fresh one placed in a wooden frame, and the used papers at once burned. To have perfect sanitation and make the place clean and free from promiscuous spitting, cuspidors must be given regular and careful consideration. Other measures that often command attention are of less importance than this as regards industrial sanitation.

The Talk of Dr. Myerson on Mental Hygiene

"Mental Hygiene as a Factor in Safety and Industrial Relations" was the subject of the address of Dr. Abraham Myerson, professor of neurology, Tufts Medical School, before the Boston Employment Managers' Association, February 12, 1921. He stressed the importance of the study of the individual, no present scientific knowledge guaranteeing an employment manager success in sizing up an individual for placement by any short cut method. He pointed out definite ways in which a psychiatrist can further mental hygiene in industry—both management and men themselves needing psychiatric advice from time to time. General paresis and epilepsy were cited as concrete illustrations of this point.

It is significant that as a result of this address one employment manager present arranged for Dr. Myerson to address his seventy-five employees a month later on "Mental Hygiene." The question period afterwards indicated keen interest in the address on the part of the employees. The first question asked as a joke, "How can one tell in advance if one is marrying an irritable husband?" and answered in similar vein, led to a number of questions of weight, and, though a movement to adjourn was made and seconded, questions continued, no one leaving until all had been answered.

This is the first instance that has come to our attention of an address on "Mental Hygiene" before a group of employees in industry, and employment managers themselves have been audience to but few and these only in the past year. The movement for a mental hygiene of industry is a new one and promises to keep industrialists busy following its progress. A wider application of the principles of mental hygiene to industry will do away with haphazard placement through the scientific ap-

preciation of the relation of the mental level of the worker to his efficiency, of his emotional stability to labor turnover, and of mental fitness and adaptability to unrest.

Madame Curie, at Work in Her Laboratory

Mme. Marie Curie, the discoverer of radium, is shown in her Paris Laboratory. The discovery of radium, a notable achievement in itself scientifically, marked a point of new departure in scientific inquiry, especially as pertains to cancer research. Madame Curie is now in the United

States. She is being entertained by representative professional people and will be given the opportunity to inspect the various centers of research in the United States. It is expected that she will avail herself of some of the advantages offered in the way of experiment, and that new activities will result from the inspiration of her visit.

Belgian Exchange Students

The Commission for Relief in Belgium Educational Foundation announces that of twenty-four students at work in American universities, ten are studying medicine. Five came from Brussels, two from Louvain, two from Leige, and one from Ghent. The students are now at Johns Hopkins, California, Harvard, Columbia, University of Pennsylvania, Cornell, Yale, and Stanford. They are specializing in stomatology, neurology, bacteriology, ophthalmology and surgery.

Through an exchange arrangement, forty-eight graduate students, twenty-four from each country, America and Belgium, study in various educational institutions.

FRANCIS D. PATTERSON, M.D.

TENTATIVE PROGRAM

American Association of Industrial Physicians and Surgeons

Boston, Mass., June 5 to 7, 1921.

SUNDAY—JUNE 5—4 P. M.

Meeting of Board of Directors at the Copley Plaza. (Guests of Dr. Patterson.)

MONDAY—JUNE 6—9 A. M.

Business session—Amphitheater, Harvard Medical School.

(1) Report of Board of Directors, by Otto P. Geier, M.D., Cincinnati, O.

(2) Report of Secretary-Treasurer, by F. D. Patterson, M.D., Philadelphia, Pa.

(3) Reports of Committees.

(4) Appointment of Nominating Committee.

(5) Appointment of Resolutions Committee.

(6) Appointment of Auditing Committee.

Adjournment for Lunch.

MONDAY—JUNE 6—2 P. M.

Amphitheater, Harvard Medical School.

(1) Presidential Address, by Otto P. Geier, M.D., Cincinnati, O.

(2) Our False Standards of Disability in Industry, by W. Irving Clark, M.D., The Norton Company, Worcester, Mass.

Discussion led by L. R. Daniels, M.D., Hood Rubber Company, Watertown, Mass.

(3) Posture in Its Relation to Industrial Efficiency, by Joel Goldthwait, M.D., Boston, Mass.

(4) The Role of a University in the Development of Industrial Hygiene, by Cecil K. Drinker, M.D., Industrial Hygiene, Harvard Medical School, Boston, Mass.

Discussion led by Dr. F. E. Schubmehl, General Electric Company, West Lynn, Mass., and J. A. Watkins, M.D., The Lukenheimer Company, Cincinnati, O.

MONDAY—JUNE 6—5 P. M.

Smoker (informal) as guests of Division of Industrial Hygiene, Harvard Medical School, Boston, Mass.

MONDAY—JUNE 6—7 P. M.

Banquet of guests of Associated Industries or Employment Managers' Association, Boston.

TUESDAY—JUNE 7—9 A. M.

Amphitheater, Harvard Medical School.

(1) Nurses in the Guise of Industrial Physicians, by W. A. Sawyer, M.D., Eastman Kodak Company, Rochester, N. Y.

Discussion led by J. T. Black, M.D., commissioner of health, State Capitol, Hartford, Conn., and John F. Curran, M.D., The Norton Company, Worcester, Mass.

(2) Study of Industrial Absenteeism, by R. S. Quinby, M.D., Hood

Rubber Company, Watertown, Mass. Discussion by F. L. Rector, M.D., Conference Board of Physicians in Industry, New York; and Edgar Seydenstricker, M.D., United States Public Health Service, Washington, D. C.

(3) Prevention of Infection in Industry, by A. J. Lanza, M.D., Hydraulic Steel Company, Cleveland, O.

Discussion by Wade Wright, M.D., Harvard Medical School, Boston, Mass., and V. A. Paul, M.D., Yale and Towne Manufacturing Company, Stamford, Conn.

(4) Heart Disease and the Ability to Work, by William Egbert Robertson, M.D., Philadelphia, Pa.

Discussion by Alfred Cohn, M.D., Rockefeller Hospital, New York; and Paul D. White, M.D., General Hospital, Boston, Mass.

TUESDAY—JUNE 7—2 P. M.

Amphitheater, Harvard Medical School.

(1) Report of Nominating Committee.

(2) Election of Officers.

(3) Report of Resolutions Committee.

(4) Report of Auditing Committee.

(5) Miscellaneous Business.

Symposium on Community Relations of Industrial Physicians.

Partnership Between the Industrial Physician and the Private Practitioner, by C. C. Burlingame, M.D., Cheney Brothers, South Manchester, Conn.

Relations with the Hospitals, by W. O. Sherman, M.D., Carnegie Steel Company, Pittsburgh.

Relation of Private Practitioners, by Dr. Charles E. Morgan, Somerville, Mass.

Relationship of the Insurance Practitioner, by George Tucker, M.D., Aetna Life Insurance Company, Hartford Conn.

Open Discussion.

C. C. BURLINGAME, M.D.,

Chairman Program Committee.

Announcement is made of an arrangement just made which brings into conference the American Association of Industrial Physicians and Surgeons with the Boston Employment Managers' Association and the Associated Industries of Massachusetts at a dinner and joint session on the evening of Monday, June 6, at the Copley Plaza Hotel, Boston, Mass. Speakers have not been announced, but the general topic of the program will be the attitude of industrial management toward health service and the point of view of the industrial toward industrial management.

Your Secretary is most disappointed over the fact that our membership does not seem to be increasing.

What are you doing to get us the right sort of new members?

Make your plans to come to the Boston meeting and make it the best meeting we ever had.

New York Industrial Nurses' Club Organize

Through the efforts of Miss Margery Lewis, a graduate of Presbyterian Hospital, the Industrial Nurses Club was organized November, 1920. The organization was completed in February, 1921, when officers were elected and a constitution and by-laws adopted.

The following officers were elected to serve until the next Annual Meeting, May, 1922: president, Mrs. Fred'k J. Brockway, Metropolitan Life Insurance Co., 1 Madison Ave., New York City; vice-president, Miss Elizabeth Burns, Ladew Tannery, Newark, N. J.; secretary, Miss Margery Lewis, C. Kenyon Company, Brooklyn, N. Y.; treasurer, Miss Mary Elderkin, Union Carbide and Carbon Corporation, 30 East 42nd St., New York City.

The Club was organized for the purpose of stimulating interest in the special problems of the industrial nurse and of providing a forum for the discussion of such problems.

Industry and the Psychopathic Employee

One of the most difficult problems dealing with psychopathic individuals and their social adjustment is their placement in work consistent with their abilities and personal peculiarities. The rehabilitation of the individual may rest upon intelligent help in his vocation, in the finding of employment, as much as upon encouragement in keeping at it. An explanation to the employment manager may be of the greatest assistance. On the other hand, if this explanation is made, the psychopathic employee may be either refused employment, or decided as hopeless at the first manifestation of difficulty. Since such individuals exist in large numbers in industry, there must be some plan created to make proper use of them through training and attention of the psychopathic worker with employment problems.

The Club meets the second Thursday of each month from October to May, inclusive; dues are \$2.00 a year; and the active membership is limited to graduate, registered nurses actively engaged in industry in Greater New York or vicinity. It is a live club, with already about seventy members. For membership blanks and information, apply to Miss Margery Lewis, R.N., Secretary, 1919 Seventh Ave., New York City.

*Current communications of interest to the membership should be addressed to the Secretary, P. O. Box No. 4061, West Philadelphia Station, Philadelphia, Pa.

Health and Working Women

THE last *Bulletin* of the Women's Bureau of the United States Department of Labor is entitled the "Physiological Basis for the Shorter Working Day for Women," by Dr. George W. Webster. Dr. Webster was a member of the Illinois Industrial Survey and this report presented by him before the Illinois Women's Legislative Congress in December, 1920, was felt by the Women's Bureau to contain such significant and valuable material that it has been reprinted by them.

Too often we lose sight of the fact that women are physically on a different plane from men, and that certain types of work a woman has no right to attempt, not only for her own sake as a citizen, but also for the sake of her children. Speed, vibration, noise, bad physical conditions as they affect the health of human beings, are community problems. The conservation of national health is much more important than the conservation of forests or coal and, unless health is guarded, not only do we suffer today, but we impose on the future an unjust and inexcusable handicap.

All laws limiting in any way the type of work, the hours of work, or the wages for work for women have been drawn up on the basis that the health of working women must be preserved. To quote from the Minimum Wage Act for the District of Columbia, we find the purposes of the Act defined as:

To protect the women and minors of the District from conditions detrimental to their health and morals, resulting from wages which are inadequate to maintain decent standards of living. . . .

The Act establishes a "Minimum Wage Board" as the machinery for determining

Standards of minimum wages for women in any occupation within the District of Columbia, and what wages are inadequate to supply the necessary cost of living to any such women workers to maintain them in good health and to protect their morals.

On the same grounds, the idea of a shorter working day for women was brought forward. Dr. Webster begins his article with a quotation from Huxley:

Women will be found to be fearfully weighted in the race for life. The duty of man is to see that not a grain is piled upon that load beyond what nature imposes; that injustice is not added to inequality.

Dr. Webster points out that science has a definite service to give to industry if an intelligent solution of indus-

trial question is sought. A standard to be truly constructive must be a scientific standard, and arguments for shortening the day of working women should be founded on a physiological basis and the fact that "they are women" should be taken fully into consideration. Industry and labor must come to have a correct conception of their relationship to society; a conception which has been proved too seldom recognized if left to contestants in unfettered individual competition.

The shorter workday is proposed in order to lessen fatigue. "Fatigue," says Dr. Webster, "like pain, is one of the great safety valves of the human machine. It is protective. It is a physical defense. Like pain, it warns of and protects against that which is worse than itself. It is a sign that one is going too fast. The human machine is subject to fatigue, the non-living machine is not."

Besides the physical or the mental labor necessary to work, *speed* is one of the chief causes of fatigue. A telephone operator carrying 225 calls per hour, or three and a half per minute, is one example of what speed in industry means. In the needle trades a girl tends a sewing machine carrying twelve needles, making four thousand stitches a minute, or 2,400,000 in ten hours, often working in a bright light and with unshaded eyes, and amidst a noise that can only be described as a deafening roar.

In a pea-canning industry a girl inspects two cans of peas per second, or 72,000 per day. The cappers place the caps on the cans at the rate of sixty to eighty per minute.

In the shoe industry a workman revolves the shoe in such a manner as to trim off the crimped surplus leather from the "upper." His task is 5,200 shoes a day.

In the eyeletting department of the shoe industry an expert worker can finish 2,000 pairs of women's shoes in one day. When it is remembered that each of these shoes has as many as twelve holes irregularly spaced, making 48,000 eyelets per day, a new idea of "speed" in industry is obtained.

Noise, ventilation, temperature, lighting, posture, etc., and other conditions involve the accumulation of fatigue, and the important thing is to measure this fatigue so that we may stop before it is too late.

It is not easy to measure industrial fatigue. In estimating output, the

speed of the machine often determines the output quantity. A superficial observer takes no account of the possible fatigue of the work showing in increased cost of labor turnover, spoiled work, accidents, illness, and ultimate injury to the workers' health. He is tied to the idea that the longer hours, the more work can be accomplished. Output in relation to the fatigue of the worker should be studied, and the estimates of output should then be used to determine the physiological standard for the days worked. In other words, a basis must be found for producing the maximum of output without overfatigue. Dr. Webster quotes from studies comparing the output of an eight and a half hour day with that of a ten hour day.

He claims as a second means of measuring fatigue, the noting of the number and time of occurrence of accidents. He quotes results of a study of Imbert and Mestre of 2,700 accidents among 60,000 workmen in various trades.

The results may be grouped as follows: (1) The number of accidents increases progressively from hour to hour during the first half day; (2) after the fairly long midday rest, in the early hours of the second half day, the number of accidents is notably less than during the last hour of the morning; (3) in the course of the second half of the day the accidents again become progressively more frequent from hour to hour; (4) the number of accidents per hour toward the end of the second half day is notably higher than the corresponding maximum of the morning.

Not only does fatigue decrease output and increase accidents, but its effect upon health is so marked that a third plan of measuring fatigue is by noting these effects upon the health of the average worker.

Workers in dangerous trades who are overfatigued are more readily attacked by occupational diseases. Overfatigue and exhaustion are permanent factors in predisposing to disease or premature death in all industries. A high labor turnover caused by sickness or discontent and an increase in the amount of spoiled work can also be charged to overfatigued workers. "Physical debility follows fatigue. Laxity of moral fiber follows physical debility," he goes on to say.

The Congress of the United States has already established the eight-hour day as the standard in government service for workers employed on government contracts, and the Federal Government is the largest em-

ployer of labor in the United States. "If individuals and firms," says Dr. Webster, "and even states, are so lacking in their social development that they are willing to sacrifice women to industrial advantage, and especially where the states fail, as five of them have utterly failed, to provide any form of protective labor legislation, is unsatisfactory and inadequate, then organized society must take action."

Not only must organized society protect women as workers, at least as much as men, in their inalienable right to the joy of labor, but it must protect itself from any of the evil or sinister effects connected with their labor as women. This is not, and cannot be, purely a personal matter between employer and employee, as the former would try to make us believe.

Owing to the complexity and variation in the character of industry and the strains in it, it is apparent that it is impossible to make a standard of hours for each industry, based on fatigue, but it is possible to have two or three levels or standards of hours, dependent upon the physical and psychological strains of the industry.

Science must be applied not only to immediate economic needs, but also to greater individual and racial resistance to disease, for the quality of our citizens will determine the character of our civilization.

Surely it is not enough that a woman is able to endure the hardship and fatigue of a ten-hour day and not die. Life for a woman should mean more than wage earning, and women should, and do, mean more to our country than mere machines. We should see to it that while engaged in the industries her hours of labor are short enough to enable her to develop into a normal, healthy, valuable member of society.

The sciences of physiology and psychology, the law, the decisions of the courts, the police power of the states, the example of the Congress, the peace conference, the joint interests of both employer and employee, the rights of society expressed in the voice of an enlightened social conscience, all unite in favoring the establishment of the eight-hour day as the maximum which should be required of women in industry. For upon the women depends the vigor of the race, and it must not be exploited for racial day purposes instead of for racial conservation.

*Bulletin No. 15, February, 1921.

Appointments to Red Cross

The Red Cross *Bulletin* of March 28, 1921, announces the fact that President Harding has appointed Eliott Wadsworth, member of the Central and Executive Committees of the Red Cross, as Assistant Secretary of the Treasury in charge of foreign loans; and W. W. Husband, assistant Service Organization, as Commissioner General of Immigration.

Housing by Employers

Magnuson* has made an important investigation of housing by employers in the United States. Employers' or company housing is a term used to describe housing work done by its employers in the interest of their employees. The employers' interest is incidental, not primarily that of a real estate operator or builder, and must be carried on as an integral part of the main business. Company housing is not a new thing. When the colonial manufacturer had located water power for his plant, the undeveloped character of the country forced him to provide housing accommodations for the labor he brought to his establishment. Some of the New England mill towns date back to 1791. The earliest cotton mill community was found in Wilmington, Del., established in 1831, most of the houses of which had been built between the years 1850 and 1860; a South Carolina community was established in 1845; one in Georgia in 1850; and another in 1856. More recent developments have taken place in the iron-mining region of Wisconsin and Minnesota, the coal fields of Ohio and Indiana, and in the western metal-mining regions. During the war the housing shortage became acute and gave rise to considerable building by employers.

The object of the investigation was to study the best and most representative work being done by employers to provide housing accommodations for their employees. Two types of communities, the mining and manufacturing towns, have been covered. This includes the cotton-mill towns of New England and the South, the steel towns of Pennsylvania, Ohio, Alabama, and Minnesota; the bituminous and anthracite coal districts; the copper towns of Northern Michigan, Wisconsin, and Minnesota; coal and iron mining towns in Alabama; the coal and metal mining towns of Colorado and Wyoming and the copper and metal mining districts of Arizona.

The report includes matters which relate to the house, its plan, construction, size, number of rooms, state of repair, sanitary equipment—its adequacy for proper housing. Some attention is given to town planning, street, and lot arrangement; the cost as shown by annual maintenance and repair charges; the methods of conducting the housing works, the rea-

sons for engaging in housing and the results from the point of view of the employer. Two hundred thirteen companies operating 423 different establishments, employing 462,991 men, of whom 160,645, or 34.4 per cent, were occupying company houses, were scheduled in 1916.

Company Town Communities

The company town is characterized in a way by a tendency to erect houses of similar plan and type; a disregard of the possibilities of architecture, town planning and beautifying through landscape gardening. As a rule, they are not crowded, but are without many such improvements as sewers, water, paved streets, and sidewalks. General community functions, such as street cleaning, lighting, health and sanitary regulations, and policing are in the hands of the controlling company. There is a distinct absence of self-government.

Rents are as a rule moderate. Of 17,643 four-room dwellings, 29.8 per cent rent for less than \$5.00 a month; 39.5 per cent for less than \$6.00; 58.1 per cent for less than \$7.00; and 76.3 per cent for less than \$8.00.

The cost of the semi-detached houses in the Pennsylvania and Virginia mining regions ranges from \$600 to \$800 per dwelling. The same thing in Michigan, 1907, cost \$825. The same detached frame cottage in New England in 1914 cost from \$800 to \$1,000 per dwelling. The four-room miner's frame house in Ohio cost \$600 to \$800, in Colorado in 1914, \$750 each. A cement block house of four rooms in Colorado cost \$650 in 1914. A four-room one-story family house of the ready-built type in Virginia in 1913 cost \$1,500. A four-room, one-family, frame bungalow, neither ceiled nor plastered inside, but having inside sanitary conveniences, erected by companies in Arizona, cost \$1,000.

The cost of housing to the employer is about \$383 per employee house, on a basis of the original cost of houses alone. Reports for eight different coal companies in Pennsylvania show a gross return of 11 per cent on a total inventory value of \$2,855,912. The gross returns vary from a maximum of 20 per cent of certain mining companies in Alabama to 6.2 per cent on houses belonging to given steel companies in Pennsylvania and Ohio. A comprehensive housing policy would standardize the work, keep down costs, and redound to public good.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

The Rooming House and Its Problems*

Modern Community Life as It Affects
the Lot of the Submerged Tenth

BY CHARLES V. CRASTER, M.D., HEALTH OFFICER, NEWARK, N. J.

MODERN community life, reacting, as it does, against so many of the accepted precepts of former days, has emphasized ever more clearly the old distinction between those who have and those who haven't.

In few respects is this more evident than in the trend to divide city populations into two distinct classes, the house owner or renter and the ever increasing quota of the community forced by a variety of reasons to live in furnished rooms, with or without board.

Rooming Groups Vary

This latter class or group, having lost its more or less stationary character, is extremely unstable in composition and is liable to considerable variation in response to social or economic pressure. In a broad way, the roomer or boarder very frequently is recruited from every rank of society, but in the main remains permanently so situated, or is the individual who after a period of stress or misfortune remains in the class for only a certain period of time, becoming sooner or later a person of family either as home owner or house renter. This floating population, floating in the sense of insecurity of home tenure as well as of a liability to change in nearly all its social functions, requires for its housing needs certain well defined accommodations.

In most of the large cities the wants of this class are met in every

conceivable way and with a variety of comfort as well as sanitary conveniences to meet all tastes. This wide range of purchasable accommodations graduates from the palatial hotels of the uptown sections, through the twilight zone of the family hotels and furnished rooms, to the murky atmosphere of the common lodging house and the "flop" room in saloons and charitable institutions.

Comparatively little of the real

rented room or boarding house are essentially of an emergency nature, and we may naturally expect that during a great housing shortage some relief will be found in the increased patronage of these places.

The World War was responsible for the present housing difficulties. So great was the lack of houses and apartments during and after the world war that undoubtedly there must have resulted considerable congestion in some localities in cities, especially in the cheaper quarters.

The worst features of the great housing need were the innumerable instances brought to the attention of the public officials of extreme overcrowding in tenements and apartments as well as in dwellings. It has been urged that health officers were themselves derelict in failing to enforce the sanitary laws against overcrowding and that if such laws had been enforced a solution of the housing problem would have been found somehow.

Choice Between Two Evils

To this it may be said that the health officers chose the lesser evil of risking the probable bad effects of overcrowding to the very definite hardships to families camping out on streets or vacant lots. It was expected that some measure of this overcrowding must have been reflected in the patronage of rooming houses and boarding places. To ascertain to what degree this was present, and incidentally to check up on the sanitary condition of these places in the city of Newark, a short survey was

Ignorance, poverty, and a home like this make it somewhat hard for the new baby.

floating population is carried by the larger hotels whose clientele is transient, although there are a few small family hotels which specialize in permanent boarders with more or less homelike surroundings.

By far the greater part find accommodation in rooming houses, with a small proportion of a seasonal class finding precarious homes in the common lodging houses of the city. The accommodations, therefore, provided for the shifting population of the

*Read before the Seventh Annual Conference on Tuberculosis, Lakewood, N. J., October 21, 1920.

What failures in health, what faults of character may find their source in an environment of combined disorder and squalor?

This is the rear elevation of a rooming house. The citizenry can scarcely be expected to rise above living conditions like this.

undertaken during October, 1920. The number of houses let in rooms and boarding houses surveyed was 137. The total number of rooms inspected was 1,997, and the number of boarders or lodgers involved was 1,904. This gives an average of about one person per room, a good margin of accommodation. In these houses there were 135 resident families, and of these twenty-five families were waiting for houses. The number of permanent boarders was placed at 1,540, representing 80 per cent of the total number. The transients so stated were only recorded at 364. In five instances overcrowding to a dangerous degree was reported by the inspectors. Rigid supervision is especially needed in the housing of foreign laborers. A degree of overcrowding was found to prevail in certain rooming houses where newly arrived emigrants were accommodated. No greater menace to life exists than in these foreign boarding houses, in which the apparent object is the imposition of the highest charges for the minimum of comfort or even decency. Conditions were found in such places apparently tolerated without protest which the average American would consider impossible. It is evident that the transient foreign laborer should be protected from the consequences of his own ignorance.

What Our Survey Showed

The net results of the survey of rooming houses did not show any considerable degree of overcrowding, and we will have to look elsewhere for any definite evidence of overcrowding in the homes of the people.

Although there can be no doubt of the fact that the house shortage has put houses let in lodgings in greatly increased demand, this has been met in the greater number of such houses in most cities. The psychology of the roomer at least demands the privacy of a single room, and only exceptionally will a rooming house owner re-

quire a doubling up as the price of his accommodation.

That extra rooming space was needed was shown by the answer to one question in the survey questionnaire: "Do you require more rooms?" answered in the affirmative by fifty-three out of 137, and in the majority of instances the same owners stated that this need could best be met by ability to make over existing houses into suitable rooming apartments.

Apart from the question of over-

This type of crowded accommodation is none too rare in rooming houses deficient in air space, light, and ventilation.

crowding, the most useful information obtained was upon the sanitary state and accommodations of houses let in rooms. The general type of rooming house lacks sanitary arrangements. The report states that generally the type of house was good, although in the greater number of instances old dwellings were in use for this purpose. Out of 137 such

houses, 84 were built of brick. Although in some ways an old house will provide suitable rooms for lodgers, there are almost insurmountable objections from the sanitary side. In nearly all the houses surveyed sanitary arrangements were described as poor. Baths and toilets were few and invariably insufficient.

Ventilation and Lighting

With few exceptions was there separate toilet accommodation provided for both sexes and, when this existed, the control was so lax as to defeat any good in the intention of the owner. Lighting and ventilation were occasionally primitive and insufficient. Fire hazards were common and the plumbing inadequate, frequently worn out and poor. In these respects the control of rented rooms is urgent. Not many months ago five Spaniards were suffocated in one room, due to a defective gas jet, and indeed few winter months go by without adding to the list of accidental fatalities from this cause.

As a result of the survey, some interesting light was shed upon the changing character of the roomers in a city. A few years ago a considerable part of our floating population was composed of Germans, Russians, Poles, Italians, and Greeks. The nationality of the 1,904 roomers in the 137 houses as far as ascertainable was as follows: Americans, 1,063; Spanish, 221; Portuguese, 178; Greeks, 62; German, 23; Jewish, 17; Italian, 16; Polish, 12; Irish, 10; Russian, 1; unknown, 301.

One important conclusion emerges as a result of this survey. The sanitary conditions found were so defective that in few instances was there really adequate or modern accommodation for the roomer in the real acceptance of the word, although no rooming or lodging house was found so unsuitable for the purpose as to require active steps to be taken for condemnation. It was evident that in

Burning rubbish found in the back yard of a rooming house. The safety of the whole community is subject to the health and fire hazard here.

The dynamic possibilities of the human mind are great indeed if they can surmount the handicap of an early experience in this type of run down rooming house.

few instances did the lodger have the use of up-to-date and easily accessible modern conveniences. It is evident that the individual seeking lodgings is long suffering and not given to public kicking at the character of the service rendered, which perhaps he looks upon as being a public reflection upon his own circumstances.

There is a very apparent need for the protection of the man who must live in rented rooms, by the adoption of definite rules and regulations to at least assure him of the common decencies of life. At the present time the accommodations offered are subject to the whim of the landlord, usually selfish and frequently profiteering. It is time the community afforded the submerged citizens some measure of protection.

The Submerged Lodger

Only by law can this long exploited individual be assured of sufficient facilities for bathing and toilet purposes as well as the requirements of elementary cleanliness in the room in which he is obliged to pass a great part of his leisure hours. The necessity for some form of legal supervision is shown by the practice in some boarding houses of allowing beds to be used by day as well as by night without any regard to the requirement of ventilation or airing or of clean linen for each occupant.

The common lodging house, once the haunt of every unnameable sanitary sin, is now kept reasonably clean by city ordinance. The same should be done for houses let in rooms. At least the minimum standard of sanitation compatible with safety is required for the benefit of a class of citizen who is largely inarticulate by reason of the necessity of accepting what is available or suitable to his earning capacity. The results of the survey are crystallized in the following draft of a suggested city ordinance or state law:

Model Law Suggested

An ordinance to provide for the licensing of rooming houses and for their sanitary condition and to protect the health of the inmates thereof.

Sec. 1.—No person, persons, firm or corporation shall conduct any rooming house without first having secured from the Department of Health, a license for that purpose and paying therefor a fee of two dollars (\$2.00).

Sec. 2.—Every building in which three or more rooms are rented, commonly known as furnished room houses, for the accommodation of individuals for a single night or longer, such building not being a hotel, shall be termed a rooming house and sub-

ject to the provisions of this ordinance.

Sec. 3.—Each and every room rented as furnished rooms shall at all times be adequately ventilated and lighted, and under no circumstances shall there be less than four hundred (400) cubic feet of air space for each occupant of such room.

Sec. 4.—Beds which have been occupied at night shall be vacated by 10 a. m., and all bedding thereof shall be turned over and exposed to the air from 11 a. m. to 4 p. m., at which time the windows of the room shall be open to the air. No room shall be rented to two different parties within twenty-four hours.

Sec. 5.—All beds, bed clothing, mattresses, and pillows shall be at all times kept clean and free from vermin. Sheets and blankets shall be

mission of the Department of Health.

Sec. 9.—The floors of all toilets, bath rooms, and water closets, and all landings, stairs, and hallways shall be made of impervious material and shall be kept scrupulously clean at all times.

Sec. 10.—There shall be at all times provided for the use of roomers an adequate supply of water and soap, and a sufficient number of clean individual towels for each person.

Sec. 11.—All plumbing equipment in toilets and baths and all gas and electric fixtures throughout the building shall be kept in good repair. In no case shall any gas fixture or stove be connected to the main gas supply other than by a permanent metal pipe. In no case will rubber or other tubing be allowed for gas fixtures.

Sec. 12.—Adequate fire exits and

Gypsy family in winter quarters in a rooming house, giving a touch of the East in their personal effects.

provided for each bed. Clean sheets and pillow cases shall be provided at least twice a week, if the bed is regularly occupied by the same individuals. Clean sheets and pillow cases shall be provided for each new occupant of the bed. All blankets must be washed at least four times each year.

Sec. 6.—Every rooming house shall be adequately provided with toilet, lavatory and bathing accommodation and, where both sexes are accommodated, there shall be separate toilets and bath rooms for each sex. (At least one toilet shall be provided for every ten persons.)

Sec. 7.—The walls, floors, and ceilings of each room, let as a furnished room shall be properly painted or provided with an impervious and cleansible surface, and no dilapidated or broken plaster or decayed wood shall be allowed in such rooms. All rooms shall be kept scrupulously clean and scrubbed and, where vermin are present, disinfection will be required.

Sec. 8.—No person shall be allowed to cook food in or use a furnished room as a living room unless by per-

fire escapes will be required in all houses over two stories in height. (At least one exit on each floor for every 50 persons accommodated on that floor.)

Sec. 13.—There shall be a central heating plant provided for every rooming house, and in no case will gas heaters be allowed in bedrooms.

Sec. 14.—The proprietor of every rooming house shall keep, or cause to be kept, a registry showing the name, former address, and place of employment of each roomer. The Department of Health shall have copies of these regulations printed and the same shall be displayed in every rooming house.

Sec. 15.—Any person or persons, firm or corporation, violating any section of this ordinance, upon conviction thereof shall be liable to a penalty of not less than ten dollars (\$10) or more than twenty-five (\$25) dollars for the first offense and a penalty of fifty dollars for each subsequent offense. Any license to conduct a rooming house may be forfeited for any violation of any of the sections of this ordinance or of the Rules and Regulations adopted.

Infectious Diseases at Summer Resorts

If Health Habits Lapse at Vacation Time, the Control of Summer Infections Becomes Impossible

BY D. L. RICHARDSON, M.D., SUPERINTENDENT, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

WHEN summer approaches, city dwellers begin to make plans for their vacations during the hot months. They hope to escape the heat and oppressiveness of the city in the summer. The open country with its fresh air and sunshine, the bathing and out of door sports, appeal to every human being. They are the means of making people vigorous and well.

But enthusiasm should be tempered with judgment for many summer resorts are unsafe for habitation, far less safe than the city. All the good such resorts may do, may be undone by the infectious diseases which often flourish. This is particularly so of intestinal diseases such as typhoid fever, dysentery, and infectious diarrheas. The danger arises from the lack of safe water and milk supply and of the proper disposal of excreta. These dangers are much less among isolated cottagers on the shore of a lake or sea or inland; likewise the danger is slight "back in the woods" where hunters and fishermen go; but constitute a very great menace to large cottage colonies, many of which are crowded.

The first question a person should ask before deciding on a place to spend a vacation is whether proper measures are taken to protect the resort against infectious diseases, emphasizing particularly the inquiry into the character of the water and milk supply and into the manner in which excreta are protected and disposed of.

A physician should also be within calling distance of such places, for infectious disease may need prompt diagnosis and isolation, a fact which should be considered, especially when the vacation is for the whole summer and there are children in the family.

Eliminate Typhoid Danger

All vacationists should receive typhoid vaccine before leaving for summer vacations. The vaccine is a solution of dead bacilli and in it should be included typhoid bacilli, together with both alpha and beta paratyphoid organisms. Three doses are required, each given at weekly intervals. The vaccine should be fresh

and obtained from a reliable source. The immunity lasts for at least two or three years and may last much longer. The United States Army gives only two series of injections, the first at the time of the first enlistment and the second at the time of the first re-enlistment, three years later.

Summer resorts vary in character and size and to some degree such variations must find a parallel in the suggestions for preventing infectious disease. Some of the more expensive resorts are in reality cities, provided with all the conveniences of a city. The resorts which fall into this category, however, are not numerous. Generally speaking, summer places constitute groups of frame houses not provided with piped water supply or flush toilets, and they closely resemble in their sanitary provisions the character of farms and small town residences. Combined with these, and occasionally in a separate location, are tent colonies. The recommendations in this communication apply to resorts of the last two mentioned kinds, for nothing need be said of the summer colonies which are really small cities.

The function of inspecting and laying down rules of sanitation of summer resorts should reside in the state boards of health. It is their duty particularly to safeguard the milk and water supply and to see that excreta are properly disposed of. In case of an outbreak of infectious disease, then State Board officials should take the problem in hand and insist on proper measures, unless perchance the resort fall within the jurisdiction of a city health department.

Usually the water supply is from wells. It is safest that these be artesian wells and they should not be situated near a privy. They should be well curbed so that pumped water will not run back into them, and no common drinking cup should be allowed at the pump. If water is taken from a lake or river on which are situated habitations, investigation should determine whether excreta are carelessly disposed of, making possible the pollution of the water supply. For campers in the woods the

danger from such a supply is very remote unless there are other camps above. It is not bad tasting water that is dangerous, but water contaminated with human excreta. Boiling drinking water is the safest procedure when any doubt exists about its character.

Standards That Safeguard

Privies should be outbuildings, and not attached to the house. They should be placed as far as possible from the well, and at a lower level. Road dust, sand, or loam should be sprinkled into the vault at least once a day. Chlorid of lime is of some value as a disinfectant and deodorizer. The vault should be at least four feet deep. It should be tight enough to keep out flies and should not be allowed to overflow, but be cleaned out once or twice a year. The window should be screened, and it is best to have the door screened, although if the latter is kept constantly closed screening may not be necessary. There are on the market chemical closets which have been quite generally used in the South and found to be efficient and practicable. They consist of tight metal tanks in which is placed a disinfecting solution into which excreta fall. The solutions recommended are lye and chromate of soda. These tanks are so arranged that they can be easily emptied and new chemical solution is then added. The cost is moderate. After defecation and urination the hands should be washed.

The milk supply is usually derived from neighboring farms. The cow stables should be kept clean and the milking done in a clean manner and by healthy people only. It should be cooled at once and, when received at the cottage, should be kept on ice or in a refrigerator. The importance of a safe milk supply cannot be too much emphasized, for babies and small children are often numerous in summer resorts; furthermore, the sojourn at the resort is during the time of the year when babies and children are most prone to intestinal infection.

It is often difficult to make sur- of a safe milk supply. Unless the

farms are under good supervision by the state board of health, cottagers have little authority to insist on proper rules. Moreover, the ice supply and refrigerators are not always what they are in the city. It is probably safer to boil all milk intended for feeding the babies.

If garbage is not regularly collected at the resort it is best to dig a hole in the ground in the back yard some two feet deep and four or five feet square. After each meal the swill is to be emptied into it and enough dirt thrown in to cover it, the pit being extended as needed.

Waste from the sink and other soiled water should be thrown into a stone pit. This pit should be beside the cottage so that the sink pipe may empty into it. It should be dug about

three feet in diameter and four feet deep and filled with round stones. The water will leach away rapidly and a bad smelling and wet spot avoided.

The cottages should be screened with cloth or wire netting, at least eighteen mesh screening used. Such netting will keep out mosquitoes as well as flies. This has an important bearing upon the comfort of the vacationists, and in malaria districts will help to prevent that disease, for the *Anopheles* mosquito is chiefly a night flying insect.

If an infectious disease develops, it is not often wise to attempt to care for the patient in such temporary surroundings. Usually the cottage is crowded and the facilities for caring for the sick rather meager. The patient should be taken home or to a

hospital. It is important that infectious disease be recognized promptly, for the time which is frequently lost may result disastrously in such diseases as diphtheria and epidemic meningitis. Safety demands that a physician always be called promptly in all acute illness of children.

In the event of infection all the members of the family, and other contacts of the patients should be examined for the detection of carriers, mild overlooked cases or frank exhibitions of the same disease. The same methods of control, in a word, should be followed as in town or city, except that the sick should not be treated in the cottage. In case of an outbreak of any infectious disease the state or nearest city board of health should be notified at once.

Health Matters Concerning the Summer Camp

BY CAPTAIN F. L. BEALS, U. S. A., CHICAGO, ILLINOIS

THE summer camp is the logical outgrowth of an inherent gypsy trait which leads everybody to love the fun of camping out. The nomadic, care free existence of the camper, who goes from one place to another, setting up his tent and building his campfire at a new spot each evening, is a lure that brings thousands to the open country and has made of Americans, in general, a nation of campers out at certain periods of the year.

The moving camp has its drawbacks, however, and the runabout vacation has come to be displaced by the vacation encampment at some spot chosen for its climate, its scenery, or its proximity to some interesting location.

Up to within recent years, the site of the camp has been the chief attraction. Whether by lake or river, in the spreading forest or the open country, the site of the camp has been chosen because of its natural surroundings and its beauty, without particular regard to the healthfulness advantages of the location. Fortunately, it is usually the case that any well selected outdoor location is normally a healthful spot, but even the high ratio of hit-or-miss healthfulness does not preclude the possibility of trouble. Infected water supply, bad drainage or improper sewage disposal may turn a beauty spot into a plague spot.

Inasmuch as the furtherance of health is one of the prime reasons

for the summer camp, it is well worth while to place emphasis upon the health conditions surrounding the camp. Nothing should be left to chance that can be ascertained by research in advance. Healthfulness of surroundings should be considered a more essential quality in the selection

the commanding officer and chief executive.

Camp Roosevelt is located five miles from Muskegon, Mich., which is a night's ride by steamer from Chicago. The choice of the site of Camp Roosevelt was not made in a desultory fashion. Our committee went over several possible sites, all of them almost equally picturesque in appearance, and finally settled on the present location, which is at least partially shown in the accompanying illustrations. The decision rested, in the final analysis, upon the fact that the present site has all essential health advantages.

Through the cooperation of the city health department of Muskegon and the city health department of Chicago, a complete survey of the grounds and surrounding country was made by experts before the camp site was formally chosen. This survey included not only the immediate site, but the surrounding country. We wanted to be absolutely certain about such things as water supply, bathing facilities, drainage, sewage disposal, freedom from mosquitoes, and the like before bringing a thousand boys into camp for a summer of recreation, health training, and education.

One of the requisites of a healthy camp is the right kind of soil. At Camp Roosevelt, the soil is sandy and no stagnant water ever collects. This condition of the soil also makes the sewage disposal easy, because the ordinary open latrine can be used

Captain F. L. Beals, U. S. A., Commandant of Camp Roosevelt.

of a camp site than the mere picturesque quality of any given location.

As a case in point, I might explain our experience in choosing a site for Camp Roosevelt, the summer camp which the Chicago Board of Education has chosen for its school boys and of which I have the honor to be

The daily program at camp includes military instruction. Here the camp paraphernalia are being given an airing.

without any of the usual dangers or disadvantages. The sandy soil, which dries quickly even after a heavy rain, eliminates the necessity of floors in the tents, except in semi-permanent buildings.

Next after considering the type of soil, we went into the matter of water supply. Spurning the opportunity of securing a supply from the open lake, we obtained a full supply from an artesian well some six hundred feet deep and with no chance of surface contamination. Shallow wells are used to supplement this supply, the water, however, being subjected to chemical tests at least once a week. The importance of a wholesome water supply is not debatable, yet many summer camps are located without any preliminary investigation as to the character and purity of the water.

Next in order of importance in planning a camp would probably be the equipment. Luckily, Camp Roosevelt is provided by the war department with standard military equipment.

Simplicity Essential

Our boys are quartered in the large pyramidal army tents, without flooring and well ventilated. Army cots and blankets are also supplied and the boys bring their own clothing and toilet articles, all of which are inspected by the company officers at least once a week. In this connection, it might be said that the chief insistence in the matter of equipment should be for simplicity of arrangements. Elaborate bedding, superfluous blankets, excess toilet facilities, and all other unnecessary impedimenta of camp life should be eliminated.

Food is a matter of prime importance, both as to its source and its

handling. At Camp Roosevelt we have spent a great deal of time and energy in perfecting a plan to supply our mess halls with good, whole-

Each of the boys enrolled is given a thorough course in first aid. When he has successfully completed this work he is given a first aid certificate for the work accomplished.

some well cooked food of unquestioned purity. Kitchens and mess halls are semi-permanent in construction, with sidewalls, screen doors and windows, and proper ventilation. These build-

ings are at some little distance from the living quarters of the camp and are thus free from a possible source of contamination.

The storing of food in the average summer camp presents a serious problem. In our case, this has been solved by keeping the perishable foods in a refrigeration plant in the city of Muskegon and supplying the camp through motor delivery twice daily. The milk question—always a potential source of disease—we solved by deciding in favor of canned milk, rather than risk the possible sources of infection through a fresh supply.

Too much attention cannot be given to the camp menu. It is the honest presumption of a great many people that the human stomach assumes the attribute of an ostrich's stomach, once the owner goes on a camping trip. This is not the case, and the menu must be planned accordingly. Simple, wholesome, well cooked food in sufficient quantity to satisfy the normal appetite, but not enough to permit gluttony—that is the rule at Camp Roosevelt.

Next to food in importance, comes the matter of exercise. And it should be remarked at this point that careful supervision of exercise is one of the important steps in the ideal summer camp. Boys, in particular, are apt to overdo and they must be watched.

At Camp Roosevelt, the boys are under the supervision of physical directors from the Chicago schools, who see that they do not overtax their strength. Good games of all kinds, military drill, recreative pastimes, and the like are encouraged. A daily swim in the lake is a part of the routine, but care is exercised to

The well selected location of the Camp adjoins Lake Michigan. The swimming lessons are occasions of great sport.

prevent too much activity. Opportunities for rest punctuate the day's program, so that nightfall finds the boys ready for a sound sleep, but not too tired to sit for a half an hour or so for an evening lecture, the moving picture, or the entertainment which is a feature of the life at Camp Roosevelt.

Health Schedule Elaborate

We have been able to maintain at Muskegon a somewhat more elaborate health schedule than is possible in smaller camps, but the principle of caution can be observed anywhere. Boys coming into the camp are given an examination as to their physical fitness and possible breakdown under the camp routine. A hospital tent is the first tent to be put up at the camp each year, and it is kept in immediate readiness for first aid cases, while arrangements are made with a Muskegon hospital to handle anything approaching a serious condition. The Chicago first aid chapter of the Red Cross maintains three physicians and a nurse at the camp at all times to take care of any emergencies.

Luckily, however, we have had very little actual need for our hospital and its staff. The general health rules, which are fully observed, preclude any serious difficulties, and about the most dangerous troubles brought to our attention are sunburn, blistered feet, and other minor afflictions of camp life. As far as that goes, we have a weekly foot inspection to prevent any serious foot trouble or infection.

One other point, and one which has a bearing on the health of the camp, is the matter of morale. The healthy camp must have a healthy moral tone, and this is again particularly true with reference to a camp for boys. This part of our work is safely entrusted to a corps of nine or ten Y. M. C. A. secretaries who are on duty in the Y. M. C. A. hut, which is a permanent part of the camp. These secretaries supply speakers, music, moving pictures, stationery, books, laundry service and the like—all helpful forms of service which go to make camp life more enjoyable and certainly more wholesome.

That there is an earnest public response to the efforts we put forth in arranging what has been termed "a model summer encampment" is proved by the growing success of Camp Roosevelt. Established originally as a camp for the boys of the Chicago high schools, it has grown into almost a national institution, with boys

The pleasure of roughing it, wholesome companionship under wholly democratic conditions obtain in the five mess halls at Camp Roosevelt.

from many states on the camp rolls each summer. This year's camp, which will begin July 3 and continue until August 27, promises to be bigger than ever, for enrollments are already reaching my office.

The success of the camp is due in some measure to the economy of it, for only a nominal charge is made

for the bed and board of the cadets who enter, but the greatest credit for the progress of the camp must be attributed to the fact that boys and their parents know that Camp Roosevelt is a healthful, joyous, beneficial summer vacation spot for building better boys through intelligent direction of normal play activities.

Student Health Service Survey

BY WILLIAM P. EDMUNDS, M.D., UNIVERSITY HEALTH SERVICE,
ANN ARBOR, MICHIGAN

THE object of all student health organizations is to care for the sick, prevent disease, and provide proper health instruction, but there is a wide variation in the methods used and success attained by the different schools. The American Student Health Association sent a questionnaire to the large universities and colleges of this country regarding student health work for the year 1919-1920. Forty schools reported that they have definite organizations to coordinate their student health work, and their replies were grouped together and tabulated with the results shown in the following tables:

Name of Organization

Department of Hygiene.....	10
Department of Student Health....	5
University Health Service.....	5
Department of Physical Education..	2
Medical Department	2
Department of University Health..	2
College Health Service.....	2
School of Hygiene.....	1
Dept. of Hygiene and Student Health	1
School of Physical Education.....	1

Medical Director	1
Unanswered	8

How the Work Is Financed

By the University.....	12
By Student fee.....	12
By Student fee and University....	7
By University and International Social Hygiene Board.....	5
By University, International Social Hygiene Board and Student fee..	1
Unanswered	3
Largest student fee...\$10.00 annually	
Smallest student fee.. 4.50 "	
Average student fee.. 6.23 "	

The budgets reported for the year averaged \$5.26 per student, being approximately divided three-fifths for salaries and two-fifths for current expenses.

Medical Staff Personnel

Full time physicians.....	36	Schools
Part time physicians only..	4	"
Women physicians	13	"
Nurses	32	"

Minnesota differs from other schools in having one full time physician as director, and eight part time fellowships paying six hundred dollars each,

thus providing a number of specialties without excessive cost.

Dispensary Service Supplied

Thirty-four schools have dispensaries. The hours the dispensaries are open average three hours of one physician's time per one thousand students. Those supported entirely by student fee usually provide physician's service and drugs without charge, while the others ordinarily charge for drugs and in some cases for physician's service also.

Sick calls made at students' rooms.32
No charges made for such calls...22
Charging regular physician's fees.. 5
Charging \$1.00 for all calls..... 3
Charging \$1.00 for day calls and \$2.00 for night calls..... 2

The schools which charge for the room calls do so with the purpose of reducing the number of such calls upon students who could just as well call at the dispensary.

Hospital Care Provided

Thirty-two schools have hospitals and the others have arrangements with city hospitals to care for their students.

	Average No.
Patients per 1000 students during the year	266.0
Patients per 1000 students per day	3.6
Days in bed per patients.....	5.7
Influenza patients per 1000 students	70.0
Pneumonia patients per 1000 students	4.1
Deaths per 1000 students.....	0.6
Average cost per day per student	\$3.44

Medical Examinations

Practically all schools give elective courses.	

Living Conditions

Good control over the living conditions of their students—

Good in	5
Slight in	15
None in	20

Physical Education

Work in Physical Education required:	
None	1
One year	5
Two years	20
Three years	1
Four years.....	6
Average amount required 2.18 years.	
Twenty-four schools give credit for the work.	

In nine schools Student Health work and Physical Education are under one head.

Miscellaneous Provisions

Vaccination against smallpox required in	13
Typhoid immunization required in:	3
Twenty-three schools have swimming pools and there are almost twenty-three different methods of caring for them.	

In nomenclature of diseases six schools use Bellevue; five use U. S. P. H. S.; and five use International Lists Causes of Death.

The replies from forty other schools which do not have definite organizations to coordinate their student health work were tabulated and the comparison of the two groups is shown below, the first column showing those having health organizations, the second those without such departments.

	Organ- izations	No Organ- ization
Full time physician on staff	36	2
Part time physician on staff	4	18
Woman physician on staff.....	13	1
Nurse	32	18
Complete medical exam. of entering students...33	20	
Examination prerequisite for entrance	7	1
Subsequent examinations of defectives made.....	21	11
Attendance at a few health lectures required	9	8
Passing one semester's work in course in Hygiene	6	5
Passing two semesters' work in course in Hygiene	13	2
Control over living conditions of students:		
Good	5	0
Moderate	15	10
None	20	30
Average years of Physical Education required 2.18	2.36	
Smallpox vaccination required	13	4
Typhoid immunization required	3	0

Conclusions Reached

(1) Every university needs a definite organization to coordinate its stu-

dent health work. This is clearly shown by the comparison of the schools having such an organization with those not having.

(2) Student health work should be systematized. The need of this is seen in the varieties of names used to designate the organization at different schools, the several systems of disease nomenclature used, the many methods of purifying swimming pools, the lack of uniformity in the cards used for medical examinations, etc. The American Student Health Association will probably do much to clarify this phase of the work during the coming year.

(3) The sick are in general well provided for.

(4) There is great need of more follow up work with the medical examinations.

(5) There is a great lack of sufficient instruction in hygiene and sanitation. The minimum requirement should be a two hour course for one semester.

(6) There is practically no control over the living conditions of students.

All Student Health Services were probably forced to gain admittance into university life through the care of the sick, but, once established, the main work should be the prevention of disease and proper education of the student body in hygiene and sanitation.

Aid for Rural Diagnostic Clinics

Dr. Victor C. Vaughan, writing in the *Journal of the American Medical Association*, April 9, 1921, points out the fact that every legally qualified physician in the United States so far as possible should have at his service all the scientific conveniences to facilitate correct diagnosis. Every rural community should have the authority to build, equip, and maintain a community hospital, just as tuberculosis hospitals are built, receiving possibly the same support from state funds. The hospitals would have libraries and laboratories, where preventive and curative medicine could be combined. This use of the hospital would enable the rural practitioner to follow more closely the recent developments in medicine.

Symposium on Health Centers

The *American Journal of Public Health*, March, 1921, contains a symposium on the health center, giving the historical development, present status, and need for the different types.

The Hospital Library and Service Bureau*

BY DONELDA R. HAMLIN, DIRECTOR, CHICAGO, ILLINOIS.

THE Hospital Library and Service Bureau was organized by the American Conference on Hospital Service to act as a clearing house for matters of interest to those active in the hospital and public health fields. Until its establishment there had been no centralization of hospital literature in this country, no complete subject index covering current or past writings on hospital topics (aside from those made in a small way for individual use), and no extensive collection of plans, specifications, lists of equipment, and analyses based on actual operation of institutions of a type such as would be helpful to individuals, communities, and public officials responsible for the development of new hospitals, dispensaries, health centers, and allied institutions.

The Hospital Library and Service Bureau is cooperative in every essential, not only its success but its very existence being dependent upon the cooperation of those active in the field it serves. It is a central repository wherein information is so arranged and tabulated as to be made available for the use of those engaged in building, equipping, and operating hospitals, sanatoriums, dispensaries, health centers, and allied institutions.

While the Hospital Library and Service Bureau is under the direct guidance of the Conference, its immediate establishment was made possible by the financial support of national hospital, surgical, medical, and social service organizations, aided by the Rockefeller Foundation. Among the organizations which have so far contributed to the support of the Library are: The National Catholic Welfare Council, the American Association of Hospital Workers, the American Association of Industrial Physicians and Surgeons, the American Medical Association, the American Hospital Association, and the Modern Hospital Publishing Company. The American Dietetic Association has also pledged its support. While it should be understood that the Library and Service Bureau serves, gratuitously, individuals having a legitimate interest in any phase of the work which comes within its scope, it is felt that public recognition should here be given to the organizations which have aided in the establishment of this service.

The policy adopted by the Library Committee precludes the giving of advice by the personnel of the library, it being the purpose of the organization to collect and disseminate information from which the persons using the library may make their own deductions.

Particular stress is placed upon the value of our service to the small hospitals who have not ready access to reference libraries and other sources of information. Our work with these institutions, particularly those in rural communities, will have to be carried on by correspondence. Since considerably over half the institutions of the United States are of less than fifty bed capacity, some idea may be had of the extent of this field.

Material to Be Collected

Perhaps the most important feature of the work done by the Hospital Library and Service Bureau during the first few months of its existence has been the "Outline of Material to be Collected." This outline, which has been printed in the various hospital, public health, nursing, and allied journals, gives a definite idea of the type of material which will eventually be available for reference purposes. A copy of the outline will also be sent to the superintendent of each hospital, sanatorium, and allied institution in the United States and Canada, so that the personnel of these institutions may have definite knowledge of the material being collected for their use. Additional material suited to individual needs will also be collected upon request.

Building committees and committees organized for the promotion of hospital projects will be especially interested in a list, recently compiled, of approximately sixteen hundred architects serving the institutional field. This list has been made in duplicate, one copy being arranged alphabetically, the other geographically, to facilitate locating the address of any given architect, or information regarding the architects in any given community. The card list also contains information in regard to the various institutions served by each of these architects. This information is now being verified and will soon be available for general reference purposes.

Floor plans of hospitals, sanatori-

ums and nurses' homes, with photographs of exteriors and interiors, are now being received for the permanent exhibit of plans which will be maintained at the library. From this exhibit special exhibits will be prepared for national association meetings, from time to time. Floor plans will not be sent out of the Library except in the case of special exhibits at national association meetings when they will be in the care of a representative of the Library.

A valuable list which is now available in the library is a list of hospitals, sanatoriums and allied institutions of the United States, arranged according to type of service. This list has been classified by type of service rendered so that information is readily accessible as to the number and location of institutions of any given type. The list of approximately nine thousand institutions will be corrected and amplified from time to time. A similar list giving information in regard to the location and service rendered by dispensaries in various parts of the country is now in process of compilation. This will include industrial dispensaries and health centers, such as the health centers being established by the American Red Cross.

The library has on file a list of all the technical and professional journals which would be of interest to those engaged in hospital and public health work. Eventually current files of such magazines will be maintained in the Library.

Hospital reports, reports of special departments, and samples of records used in hospitals and dispensaries are being assembled. From these it will be possible to compile very valuable statistics and tabulations on the different phases of hospital activities.

A number of interesting and authoritative books have recently been added to the library, a great many of which are autographed copies contributed by the authors.

To encourage frequent conferences among hospital workers, through the formation of local associations, the Library has been placed at the disposal of such associations. The Chicago Dietetic Association meets monthly in the Library and regular meetings of the Chicago Society of Anesthetics will be held there beginning this month.

*Read before the American Conference on Hospital Service, Chicago, March 9, 1921.

A list of hospitals opened during the past year is now being made. From these lists of original equipment will be secured with an expression from the superintendent as to the adequacy of the material selected.

A tentative arrangement for the procurement of information on the laws affecting hospitals of all states, has been made for submission to the Library Committee. It is hoped that within the near future a definite arrangement may be made so that such information may be available for our clientele.

Information from national associations dealing with the various phases of hospital, public health, child welfare, social service, nursing, dietetic, medical and surgical work is now available. This information includes the purpose and scope of the associations, the personnel, time and place of meeting, requirements for admission, reports, and transactions. Close contact will be maintained with these organizations that their work may not be duplicated and that information in their files may be available for those using the library.

A card file is now being made of all institutions giving special courses in social service, public health, anesthesia, nursing, occupational therapy, physiotherapy, laboratory technic, and dietetics.

While every effort is being made to collect, as rapidly as possible, material for the Library and Service Bureau, it will be some time before all the material referred to in the outline is assembled. Despite this fact, inquiries are invited on any subject of interest to the hospital field. If the material desired is not immediately available, every effort will be made to secure it as promptly as possible.

Brief Statement of Purpose

The Hospital Library and Service Bureau is under the direction and is an important part of the American Conference on Hospital Service.

It belongs to the constituent members of the Conference.

It was established to act as a clearing house on all phases of hospital and public health work.

It will serve all persons actively engaged in such work; for instance, it will serve not only the superintendent of the hospital but the superintendent of the training school, the dietitian, the social service worker, and the heads of similar departments.

Its service is free. The more it is used the more valuable it will become through material collected to answer inquiries.

It does not give advice. That aid may be given in solving the problems of administration which may arise, the Library will endeavor to learn how other hospitals have met such problems, and the information thus secured will be transmitted to the person making the inquiry.

Members of the Conference are invited to study the "Outline of Material to be Collected," copies of which are supplied upon request, and to send suggestions for amplification of the Outline to meet individual needs. The outline in its present form is merely a chart of material to which it is proposed to add from time to time.

Relief Associations Among Government Employees

Eighty organizations which maintain funds for the purpose of furnishing financial assistance to members in case of sickness or death were included in a study reported in *Bulletin* No. 282, Bureau of Labor Statistics. Fifty of these paid sick benefits only, fourteen death benefits only, and sixteen on the basis of sick benefit societies pay sick and death benefits. Twenty-eight operate in the Navy Yard, twenty-three in the Government printing office, and one each in twelve other departments, offices, and

bureaus. The membership covered 23,171 men and women, with the total receipts of \$256,013.92, while the seventy-seven societies reporting paid \$1,132,320.05 in sick and death benefits. All but two paying sick benefits distribute their surplus funds at the end of each year to members who have not drawn sick benefits of the sixty-six paying such dividends; sixty-one disbursed \$77,681.91. Fifty associations provided relief in sickness only. Forty-six reported total receipts of \$100,296.16, over 96 per cent of which was paid to members either as sick benefits during the year (\$46,289.62) or as dividends at the end of the year, \$50,129.43.

The amount of sick benefit ranges from four to thirty dollars per week for from four to ten weeks, with a waiting period of from one week to six to twelve working days. No sick benefit is paid for less than one week. The largest amount of relief possible from a single membership is \$192 for the association year. The death benefit varied from \$50 to \$300. After the first week of sickness—two weeks in a few associations—sick benefits are paid weekly, while the beneficiaries in case of death benefits often receive the amount due them within a few hours after the death of the member.

Prominent Physicians Visit the President

A number of prominent physicians were recent guests at a luncheon with President Harding at the White House. This photograph shows the guests leaving. They are from left to right: Surgeon General H. S. Cumming, U. S. A.; Dr. Charles Mayo of Rochester, Minn.; Dr. C. E. Sawyer, the President's physician; Dr. W. F. Snow; Rear Admiral E. R. Stitt, Surgeon General of the Navy; Dr. Edward Martin, commissioner of health for Pennsylvania; and Surgeon General M. W. Ireland, U. S. A.

Public Health Problems in Europe Accentuated

The Post-War Health Movement Has Made
Geneva the Health Center of all the World

BY C.-E. A. WINSLOW, M.D., GENERAL MEDICAL DIRECTOR, THE LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

IT MIGHT seem that a definite advance along public health lines would be impossible in battle-scarred Europe at the present time; and the difficulties in the path of progress are indeed very great. With the reparations question at an impasse, with Russia still practically isolated, with Austria and Hungary economically crippled, and with the terrible loss of life and property in every belligerent country, it requires courage to plan constructively for the future.

In the public health field, the menace of extensive post-war pestilence has so far been held in check. Typhus is still a grave problem in Poland and Russia and the case fatality rate this spring has been abnormally high. Nevertheless, we believe that this disease is in general under control, and well informed experts are directing their attention towards cholera, which is already prevalent in certain sections of eastern Europe as the most critical epidemic menace of the summer. The great public health problems of infant mortality and tuberculosis, which form the major task of public health in normal times, are, however, enormously accentuated at the present moment, and constitute the most outstanding challenge to the health administrator.

In Vienna, for example, the tuberculosis death rate for infants under one year of age was 608 per 100,000 in 1919, which was not far from the

normal figure before the war. Between the ages of one and four years, however, the rate has risen from 437 in 1913, to 679 in 1919. Between five and nine years it has risen in the same six year period from 138 to 286, and between ten and fourteen years from 92 to 194. Mr. Knud Stouman estimates that in the eleven newly formed countries of central Europe the tuberculosis death rate for all ages ranges between 300 and 600 per 100,000, which corresponds to some 400,000 deaths per year.

In spite, however, of these tremendous handicaps of post-war disorganization, a survey of the whole field indicates that the public health program as a whole is making real progress in Europe and that in the next five years we may look for a more general and vigorous campaign against disease than has ever been waged before.

In England the Ministry of Health is carrying out Sir George Newman's admirable plans of constructive health development along broadly conceived social lines. The infant welfare work which was so stimulated during the war has brought down the infant mortality rate for England and Wales to 80 deaths under one year per thousand living births for 1920, as against 89 for the previous year and 108 for 1913. Campaigns against tuberculosis and venereal disease are also being developed with remarkable effectiveness, and alto-

gether England is probably leading the world in public health activities at the present moment.

In France, there is unusually active interest in child welfare work, and Americans may be proud of the splendid organization developed by the Rockefeller Foundation under Dr. Linsly Williams, which is extending its field to include not only tuberculosis, but also a far reaching plan of propaganda in regard to the wider problems of general public health.

In Italy there are interesting reactions between the public health campaign and the labor movement which promise much for the progress of industrial hygiene and which have recently crystallized in the establishment of an institute of public health with vast plans for coordinating and developing public health propaganda under the leadership of Professor Etto Levi.

The Movement Widens

The stirring of the impulse toward a widening and deepening public health movement is by no means confined to the larger countries. In Czecho-Slovakia the Ministry of Health, under Dr. Prochaska, and the Czecho-Slovakian Red Cross under Miss Alice Masaryk, are both developing the keenest interest in the possibilities of "the new public health." Professor S. M. Gunn is in Prague representing the Rockefeller Foundation as a special health adviser to the

government; a mission of eminent health experts has just returned from an inspection trip to America full of enthusiasm for health education; and the League of Red Cross Societies is cooperating with the Czecho-Slovakian Red Cross in a model child welfare demonstration in Slovakia and in the operation of a demonstration health propaganda unit which has just begun its work in Prague. All in all, Czecho-Slovakia promises to be a center of inspiration for the whole region of central Europe along health lines.

In Jugo-Slavia, too, the Ministry of Health has recently formulated a program of public health education which is relatively the most ambitious yet undertaken in any European country; and a most admirable piece of child welfare work is being conducted by the Serbian Child Welfare Association, directed by Dr. R. R. Reeder, with finances derived chiefly from the United States.

Poland is more heavily handicapped by recent war conditions than most of its neighboring states, but even here it is encouraging to note that an admirably organized public health laboratory has been developed by Dr. Rajchman, which is supplying not only Poland, but other countries as well, with excellent sera and vaccines.

In Roumania an extensive plan for child welfare work is being organized by the Prince Mercea Society and the League of Red Cross Societies is cooperating in this field, as well as in that of nursing education. In the Baltic States, Dr. Ryan of the American Red Cross is carrying on a magnificent health program which is also particularly concerned with child welfare.

In connection with the vital problem of nursing education it should be mentioned that the American Red Cross is operating a training school in Prague and two training schools in Poland which, with the school in Bucharest, and the projected school in Belgrade, are likely to exercise an incalculable influence on the development of public health nursing in central and eastern Europe. The international school of public health nursing organized by the League of Red Cross Societies in London will send back its first crop of graduates in June to take an active part in the front line activities of this sector of the public health campaign.

In the southern countries of Europe there is much interest in the malarial problem, and one particularly important demonstration is being carried

on in Spain in cooperation with the League of Red Cross Societies.

Rural Hospital Units

In this brief review we have been concerned with notable new developments, but it should be mentioned that the normally admirable health activities of the northern states of Europe are making steady progress, a particularly interesting aspect of the work being the organization of small hospital units for rural districts in Sweden and, to some extent, in Norway, by cooperation between governments and the national Red Cross societies. In Switzerland, which has been the home of so many educational movements, interest has been aroused in the question of training the personnel needed for administrative health work, and comprehensive plans are under way for the development of special courses along this line at the universities of Zurich and Lausanne.

The little city of Geneva is naturally an active center for the exchange of health information, and the stimulation of health activity, for the whole of Europe, since there are here in operation three important international bureaus all of which are more or less directly interested in the public health movement. The League of Red Cross Societies, inspired by the vision of Mr. Henry P. Davison, embodies a new voluntary movement for the development of public health through the medium of Red Cross societies throughout the world. The International Labour Bureau, although a branch of the League of Nations, constitutes practically a separate organization dealing with the great problems of industrial life and having large potentialities of service in the health field. And, finally, the League of Nations itself has practically completed the organization of a technical committee on health which will be in position to coordinate and extend governmental procedure in regard to international health questions so as to bring in a new era in the field of international quarantine.

The shadow of the war is still dark on this continent, but the nations are earnestly at work, at home on local problems, and in the councils of the Leagues upon the vastly more difficult problems of international co-ordination; while among both national and world problems, public health is taking a prominent place. The broadened vision of the situation gives the best assurance of a consistent attack upon the whole problem.

Dr. Carlos Chagas Visits the United States

Another distinguished visitor has recently come to the United States in the person of Dr. Carlos Chagas of Rio de Janeiro, director of the Brazilian Department of Public Health, one of the eminent medical scientists of South America. Dr. Chagas is

the discoverer of the parasitic malady technically known as "Chagas' disease." Rio de Janeiro has been freed from yellow fever during the period of his association with Oswaldo Cruz, whom he succeeded as director of the Oswaldo Cruz Institute for Medical Research. In connection with the hookworm campaigns and other activities of the International Health Board in Brazil, Dr. Chagas has proved a wise counselor and loyal supporter. He comes to the United States as the guest of the International Health Board and the Rockefeller Foundation, his objective on this trip being to familiarize himself with important phases of medical and public health training and to survey matters which have a bearing upon his administrative public health work in Brazil.

The coming of Dr. Chagas must be regarded as an event of great importance in the progress of preventive medicine. His training and experience fit him in a peculiar way to add to the world's knowledge of certain diseases and the best means of combating them. His lectures at Johns Hopkins University and at the Harvard Medical School will be of distinct value to the theory and practice of hygiene in the United States and will suggest measures which should serve to bring closer together the two countries in higher ideals of scientific method in the practice of preventive medicine.

Effect of Recreation on the Nervous System*

Capacities Unexercised Finally Atrophy.
Look to Your Leisure for Development.

BY BERENICE C. SKIDELSKY, COMMUNITY SERVICE, NEW YORK CITY

MANY years of operation and study of the nervous disorders which are among the fruits of modern civilization have enabled Dr. Charles Loomis Dana, professor of

the waking day not taken up with gaining a livelihood. In a week of 168 hours, forty-four are given to work, fifty-six are given to sleep, and sixty-eight to leisure.

"I was talking recently with an intelligent young woman who is an exponent of Socialism," he said, "who declared that the time will come when the working day will be of four hours' duration."

"But," I said to her, "what will the workers do with the rest of the time?"

"Oh, they will read—study—play, go to concerts, organize a theater of their own," she replied promptly.

"I replied, 'They will do nothing of the kind! As I see human nature in the country and our own city, they will sit at home, overeat, or smoke, go for a walk, or go to a movie, or prize fight, or ball game.'"

The average person does not know how to do the better and wiser, and really amusing things of leisured life.

"It takes a special training to live a life of leisure and amusement wisely. Here, as in every phase of life, intelligent and constructive planning is necessary to safeguard the individual against following the line of least resistance, and drifting into a diffuseness and aimlessness of attitude that leads nowhere except in the direction of disintegration."

"What might be some of these 'lines of least resistance'?" questioned the interviewer.

Underwood & Underwood.

This lively scrimmage occurred in a recent hockey match in Philadelphia. When is work not work, but play?

nervous diseases at Cornell Medical College, to speak with authority concerning their nature, causes, and cure. As a result of his observation among persons of all classes, ages, and occupations, he has arrived at certain conclusions, which he discussed in the recent interview reported in this article.

Leisure Has Its Hazards

One of the most significant of these conclusions is to the effect that idleness disorders are more serious than occupational disorders; more disorders of the mind and of the nerves arise from a misuse of the leisure time than from the exigencies of the regular work or occupation. Rapid increase in wages and wealth, also labor agitation, and the legislation which has grown out of it, have resulted in a greatly increased "leisure class," or semi-leisure class, to be more accurate. That is, shorter working hours than ever before in the world's history have brought it about that most people have many hours of

The apparent excellence of this state of things, however, according to Dr. Dana, is spoiled by ignorance of Americans of how to use leisure wisely.

Western Newspaper Union.

Quick reaction time as well as supple bodies result from the parry and thrust of fencing. Make the achievement of skill in some side line the object of your leisure pursuits.

Underwood & Underwood.

Group calisthenics may or may not constitute recreation. If corrective of fatigue postures, or if entered into with a spirit of fun, relaxation and diversion may be thus obtained.
